▲ **Figure 21.20** **Basic design of a pressurized water reactor nuclear power plant.**

The design of a nuclear power plant is basically the same as that of a power plant that burns fossil fuel (except that the burner is replaced by a reactor core). The nuclear power plant design shown in **Figure 21.20**, a pressurized water reactor, is currently the most popular. The primary coolant passes through the core in a closed system, which lessens the chance that radioactive products could escape the core. As an added safety precaution, the reactor is surrounded by a reinforced concrete *containment shell* to shield personnel and nearby residents from radiation and to protect the reactor from external forces. After passing through the reactor core, the very hot primary coolant passes through a heat exchanger, where much of its heat is transferred to a *secondary coolant*, converting the latter to high-pressure steam that is used to drive a turbine. The secondary coolant is then condensed by transferring heat to an external source of water, such as a river or lake. The cooling systems of nuclear power plants are necessary for proper and safe operation. The nuclear disaster in Fukushima, Japan, in March 2011 occurred when a tsunami damaged the reactor cooling systems, resulting in a large-scale release of radioactive materials.

Although about two-thirds of all commercial reactors are pressurized water reactors, there are several variations on this basic design, each with advantages and disadvantages. A *boiling water reactor* generates steam by boiling the primary coolant; thus, no secondary coolant is needed. The reactors at Fukushima, Japan, were boiling water reactors. Pressurized water reactors and boiling water reactors are collectively referred to as *light water reactors* because they use H_2O as moderator and primary coolant. A *heavy water reactor* uses D_2O (D = deuterium, ^2H) as moderator and primary coolant, and a *gas-cooled reactor* uses a gas, typically CO_2, as primary coolant and graphite as the moderator. Use of either D_2O or graphite as the moderator has the advantage that both substances absorb fewer neutrons than H_2O. Consequently, the uranium fuel does not need to be as enriched.

Nuclear Waste

The fission products that accumulate as a reactor operates decrease the efficiency of the reactor by capturing neutrons. For this reason, commercial reactors must be stopped periodically to either replace or reprocess the nuclear fuel. When the fuel elements are removed from the reactor, they are initially very radioactive. It was originally intended that they be stored for several months in pools at the reactor site to allow decay of short-lived radioactive nuclei. They were then to be transported in shielded containers to reprocessing plants where the unspent fuel would be separated from the fission products. Reprocessing plants have been plagued with operational difficulties, however, and there is intense opposition in the United States to the transport of nuclear wastes on the nation's roads and rails.

Even if the transportation difficulties could be overcome, the high level of radioactivity of the spent fuel makes reprocessing a hazardous operation. At present in the United States, spent fuel elements are kept in storage at reactor sites. Spent fuel is reprocessed, however, in France, Russia, the United Kingdom, India, and Japan.

Storage of spent nuclear fuel poses a major problem because the fission products are extremely radioactive. It is estimated that 10 half-lives are required for their radioactivity to reach levels acceptable for biological exposure. Based on the 28.8-yr half-life of strontium-90, one of the longer-lived and most dangerous of the products, the wastes must be stored for nearly 300 yr. Plutonium-239 is one of the by-products present in spent fuel elements. It is formed by absorption of a neutron by uranium-238, followed by two successive beta emissions. (Remember that most of the uranium in the fuel elements is uranium-238.) If the elements are reprocessed, the plutonium-239 is largely recovered because it can be used as a nuclear fuel. However, if the plutonium is not removed, spent elements must be stored for a very long time because plutonium-239 has a half-life of 24,000 yr.

A *fast breeder reactor* offers one approach to getting more power out of existing uranium sources and potentially reducing radioactive waste. This type of reactor is so named because it creates ("breeds") more fissionable material than it consumes. The reactor operates without a moderator, which means the neutrons used are not slowed down. In order to capture the fast neutrons, the fuel must be highly enriched with both uranium-235 and plutonium-239. Water cannot be used as a primary coolant because it would moderate the neutrons, and so a liquid metal, usually sodium, is used. The core is surrounded by a blanket of uranium-238 that captures neutrons that escape the core, producing plutonium-239 in the process. The plutonium can later be separated by reprocessing and used as fuel in a future cycle.

Because fast neutrons are more effective at decaying many radioactive nuclides, the material separated from the uranium and plutonium during reprocessing is less radioactive than waste from other reactors. However, the generation of relatively high levels of plutonium, coupled with the need for reprocessing, is problematic in terms of nuclear nonproliferation. Thus, political factors, coupled with increased safety concerns and higher operational costs, make fast breeder reactors quite rare.

A considerable amount of research is being devoted to the disposal of radioactive wastes. At present, the most attractive possibilities appear to be formation of glass, ceramic, or synthetic rock from the wastes as a means of immobilizing them. These solid materials would then be placed in containers of high corrosion resistance and durability and buried deep underground. The process of selecting appropriate deep repositories for high-level waste and spent fuel is now under way in several countries. In the United States, the Department of Energy (DOE) had designated Yucca Mountain in Nevada as a disposal site, but in 2010 this project was discontinued because of technical and political concerns. Unfortunately, there is now no long-term solution to nuclear waste storage in the United States.

In spite of these difficulties, nuclear power is making a modest comeback as an energy source. Concerns about climate change caused by escalating atmospheric CO_2 levels (Section 18.2) have increased support for nuclear power as a major energy source in the future, although nuclear power is still a major source of political discourse and disagreement. Increasing demand for power in rapidly developing countries, particularly China, has sparked a rise in construction of new nuclear power plants in those parts of the world.

Self-Assessment Exercises

SAE 21.17 Identify the missing product in the following nuclear fission reaction:

$$^{239}_{94}\text{Pu} + {}^{1}_{0}\text{n} \longrightarrow ? + {}^{94}_{36}\text{Kr} + 2\,{}^{1}_{0}\text{n}$$

(a) $^{144}_{31}\text{Ga}$ **(b)** $^{144}_{58}\text{Ce}$ **(c)** $^{145}_{58}\text{Ce}$ **(d)** $^{146}_{58}\text{Ce}$

SAE 21.18 Which of the following statements about nuclear fission power plants is or are *true*?

(i) One of the advantages of nuclear fission reactors is that they don't produce any waste.
(ii) The primary fuel used in nuclear fission power plants is ^{235}U.
(iii) The role of the control rods is to absorb neutrons as a means of controlling the rate at which fission occurs.

(a) Only one of the statements is true. **(b)** Statements i and ii are true. **(c)** Statements i and iii are true. **(d)** Statements ii and iii are true. **(e)** All three statements are true.

21.8 | Nuclear Power: Fusion

Learning Objective

When you finish Section 21.8, you should be able to:

- Describe the principles involved in nuclear fusion reactions.

In Sections 21.6 and 21.7, we saw that energy is released when heavy nuclei are split into smaller nuclei. Energy is also produced when very light nuclei fuse into heavier ones. Reactions of this type are responsible for the energy produced by the Sun. Spectroscopic studies indicate that the mass composition of the Sun is 74% H, 25% He, and only 1% all other elements. The following reactions are among the numerous nuclear fusion processes believed to occur in the Sun:

$$ {}^{1}_{1}\mathrm{H} + {}^{1}_{1}\mathrm{H} \longrightarrow {}^{2}_{1}\mathrm{H} + {}^{0}_{+1}\mathrm{e} \tag*{[21.26]} $$

$$ {}^{1}_{1}\mathrm{H} + {}^{2}_{1}\mathrm{H} \longrightarrow {}^{3}_{2}\mathrm{He} \tag*{[21.27]} $$

$$ {}^{3}_{2}\mathrm{He} + {}^{3}_{2}\mathrm{He} \longrightarrow {}^{4}_{2}\mathrm{He} + 2\,{}^{1}_{1}\mathrm{H} \tag*{[21.28]} $$

$$ {}^{3}_{2}\mathrm{He} + {}^{1}_{1}\mathrm{H} \longrightarrow {}^{4}_{2}\mathrm{He} + {}^{0}_{+1}\mathrm{e} \tag*{[21.29]} $$

Fusion is appealing as an energy source because of the availability of light isotopes on Earth and because fusion products are generally not radioactive. Despite this fact, fusion is not presently used to generate energy. The primary problem is that extremely high temperatures and pressures are needed to overcome the electrostatic repulsion between nuclei in order to fuse them. The lowest temperature required for any fusion is about 40,000,000 K, the temperature needed to fuse deuterium and tritium:

$$ {}^{2}_{1}\mathrm{H} + {}^{3}_{1}\mathrm{H} \longrightarrow {}^{4}_{2}\mathrm{He} + {}^{1}_{0}\mathrm{n} \tag*{[21.30]} $$

Fusion reactions are therefore also known as **thermonuclear reactions**.

Such high temperatures have been achieved by using an atomic bomb to initiate fusion. This is the operating principle behind a thermonuclear, or hydrogen, bomb. This approach is obviously unacceptable for a power generation plant.*

Numerous problems must be overcome before fusion becomes a practical energy source. In addition to the high temperatures necessary to initiate the reaction, there is the problem of confining the reaction. No known structural material is able to withstand the enormous temperatures necessary for fusion. Much research has centered on the use of an apparatus called a *tokamak*, which uses strong magnetic fields to contain and to heat the reaction. Temperatures of over 100,000,000 K have been achieved in a tokamak. Unfortunately, scientists have not yet been able to generate more power than is consumed over a sustained period of time.

---

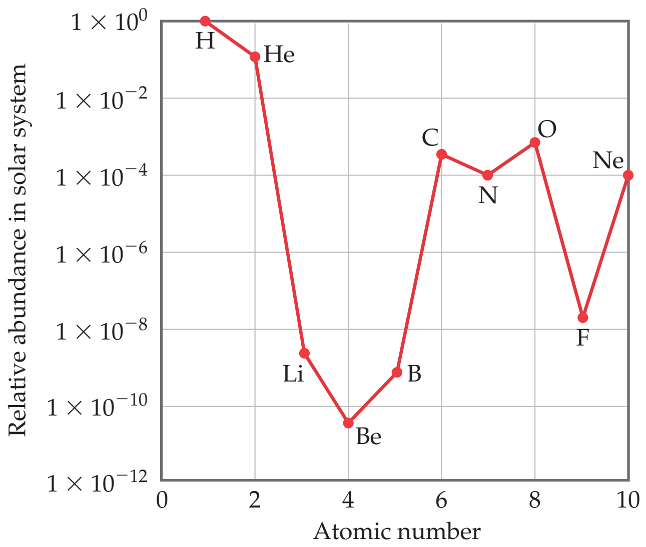
*Historically, a nuclear weapon that relies solely on a fission process to release energy is called an atomic bomb, whereas one that also releases energy via a fusion reaction is called a hydrogen bomb.

A CLOSER LOOK Nuclear Synthesis of the Elements

The lightest elements—hydrogen and helium along with very small amounts of lithium and beryllium—were formed as the universe expanded in the moments following the Big Bang. All the heavier elements owe their existence to subsequent nuclear reactions that occur in stars. These heavier elements are not all created in equal amounts, however. In our solar system, for example, carbon and oxygen are a million times more abundant than lithium and boron, and over 100 million times more abundant than beryllium (**Figure 21.21**)! In fact, of the elements heavier than helium, carbon and oxygen are the most abundant. This is more than an academic curiosity given the fact that these elements, together with hydrogen, are the most important elements for life on Earth. Let's look at the factors responsible for the relatively high abundance of carbon and oxygen in the universe.

A star is born from a cloud of gas and dust called a *nebula*. When conditions are right, gravitational forces collapse the cloud, and its core density and temperature rise until nuclear fusion commences. Hydrogen nuclei fuse to form deuterium, ${}^{2}_{1}\mathrm{H}$, and eventually ${}^{4}_{2}\mathrm{He}$ through the reactions shown in Equations 21.26 through 21.29. Because ${}^{4}_{2}\mathrm{He}$ has a larger binding energy than any of its immediate neighbors (Figure 21.12), these reactions release an enormous amount of energy. This process, called *hydrogen burning*, is the dominant process for most of a star's lifetime.

Once a star's supply of hydrogen is nearly exhausted, several important changes occur as the star enters the next phase of its life and is transformed into a *red giant*. The decrease in nuclear fusion causes the core to contract, triggering an increase in core temperature and pressure. At the same time, the outer regions expand and



▲ **Figure 21.21 Relative abundance of elements 1–10 in the solar system.** Note the logarithmic scale used for the *y* axis.

cool enough to make the star emit red light (thus, the name *red giant*). The star now must use $^{4}_{2}\text{He}$ nuclei as its fuel. The simplest reaction that can occur in the He-rich core, fusion of two alpha particles to form a $^{8}_{4}\text{Be}$ nucleus, does occur. The binding energy per nucleon for $^{8}_{4}\text{Be}$ is very slightly smaller than that for $^{4}_{2}\text{He}$, so this fusion process is very slightly endothermic. The $^{8}_{4}\text{Be}$ nucleus is highly unstable (half-life of 7×10^{-17} s)) and so falls apart almost immediately. In a tiny fraction of cases, however, a third $^{4}_{2}\text{He}$ collides with a $^{8}_{4}\text{Be}$ nucleus before it decays, forming carbon-12:

$$^{4}_{2}\text{He} + {}^{4}_{2}\text{He} \longrightarrow {}^{8}_{4}\text{Be}$$

$$^{8}_{4}\text{Be} + {}^{4}_{2}\text{He} \longrightarrow {}^{12}_{6}\text{C}$$

Some of the $^{12}_{6}\text{C}$ nuclei go on to react with alpha particles to form oxygen-16:

$$^{12}_{6}\text{C} + {}^{4}_{2}\text{He} \longrightarrow {}^{16}_{8}\text{O}$$

This stage of nuclear fusion is called *helium burning*. Notice that carbon, element 6, is formed without prior formation of elements 3, 4, and 5, explaining in part their unusually low abundance. Nitrogen is relatively abundant because it can be produced from carbon through a series of reactions involving proton capture and positron emission.

Most stars gradually cool and dim as their helium is converted to carbon and oxygen, ending their lives as *white dwarfs*, a phase in which stars become incredibly dense—generally about one million times denser than the Sun. The extreme density of white dwarfs is accompanied by much higher temperatures and pressures at the core, where a variety of fusion processes lead to synthesis of the elements from neon to sulfur. These fusion reactions are collectively called *advanced burning*.

Eventually, progressively heavier elements form at the core until it becomes predominantly ^{56}Fe, as shown in **Figure 21.22**. Because this is such a stable nucleus, further fusion to heavier nuclei consumes energy rather than releasing it. When this happens, the fusion reactions that power the star diminish, and immense gravitational forces lead to a dramatic collapse called a supernova *explosion*. Neutron capture coupled with subsequent radioactive decay in the dying moments of such a star is responsible for the presence of all elements heavier than iron and nickel.

Without these dramatic supernova events in the past history of the universe, heavier elements that are so familiar to us, such as silver, gold, iodine, lead, and uranium, would not exist.

Self-Assessment Exercise

SAE 21.19 Identify the missing product in the following nuclear fusion reaction:

$^{8}_{4}\text{Be} + {}^{4}_{2}\text{He} \longrightarrow$ ____

(a) $^{8}_{4}\text{Be}$ **(b)** $^{12}_{6}\text{C}$ **(c)** $^{16}_{8}\text{O}$ **(d)** $^{14}_{6}\text{C}$

21.9 | Radiation in the Environment and Living Systems

Learning Objectives

When you finish Section 21.9, you should be able to:

- Compare the damaging and therapeutic effects of radiation.
- Calculate a dose of radiation.

We are continuously bombarded by radiation from both natural and artificial sources. We are exposed to infrared, ultraviolet, and visible radiation from the Sun; radio waves from radio and television stations; microwaves from microwave ovens; X rays from medical procedures; and radioactivity from natural materials (**Table 21.8**). Understanding the different energies of these various kinds of radiation is necessary in order to understand their different effects on matter.

When matter absorbs radiation, the radiation energy can cause atoms in the matter to be either excited or ionized. In general, radiation that causes ionization, called **ionizing radiation**, is far more harmful to biological systems than radiation that does not cause ionization. The latter, called **nonionizing radiation**, is generally of lower energy, such as radiofrequency electromagnetic radiation (Section 6.1) or slow-moving neutrons.

Most living tissue contains at least 70% water by mass. When living tissue is irradiated, water molecules absorb most of the energy of the radiation. Thus, it is common to define ionizing radiation as radiation that can ionize water, a process requiring a minimum energy of 1216 kJ/mol. Alpha, beta, and gamma rays (as well as X rays and higher-energy ultraviolet radiation) possess energies in excess of this quantity and are therefore forms of ionizing radiation.

When ionizing radiation passes through living tissue, electrons are removed from water molecules, forming highly reactive H_2O^+ ions. An H_2O^+ ion can react with another water molecule to form an H_3O^+ ion and a neutral OH molecule:

$$H_2O^+ + H_2O \longrightarrow H_3O^+ + OH \qquad [21.31]$$

The unstable and highly reactive OH molecule is a **free radical**, a substance with one or more unpaired electrons, as seen in the Lewis structure shown in the margin.

The OH molecule is also called the *hydroxyl radical*, and the presence of the unpaired electron is often emphasized by writing the species with a single dot, $\cdot OH$. In cells and tissues, hydroxyl radicals can attack biomolecules to produce new free radicals, which in turn attack yet other biomolecules. Thus, the formation of a single hydroxyl radical via Equation 21.31 can initiate a large number of chemical reactions that are ultimately able to disrupt the normal operations of cells.

The damage produced by radiation depends on the activity and energy of the radiation, the length of exposure, and whether the source is inside or outside the body. Gamma rays are particularly harmful outside the body because they penetrate human tissue very effectively, just as X rays do. Consequently, their damage is not limited to the skin. In contrast, most alpha rays are stopped by skin, and beta rays are able to penetrate only about 1 cm beyond the skin surface (**Figure 21.23**). Therefore, neither alpha rays nor beta rays are as dangerous as gamma rays, *unless* the radiation source somehow enters the body. Within the body, alpha rays are particularly dangerous because they transfer their energy efficiently to the surrounding tissue, causing considerable damage.

TABLE 21.8 Average Abundances and Activities of Natural Radionuclides[†]

	Potassium-40	Rubidium-87	Thorium-232	Uranium-238
Land elemental abundance (ppm)	28,000	112	10.7	2.8
Land activity (Bq/kg)	870	102	43	35
Ocean elemental concentration (mg/L)	339	0.12	1×10^{-7}	0.0032
Ocean activity (Bq/L)	12	0.11	4×10^{-7}	0.040
Ocean sediments elemental abundance (ppm)	17,000	—	5.0	1.0
Ocean sediments activity (Bq/kg)	500	—	20	12
Human body activity (Bq)	4000	600	0.08	0.4[‡]

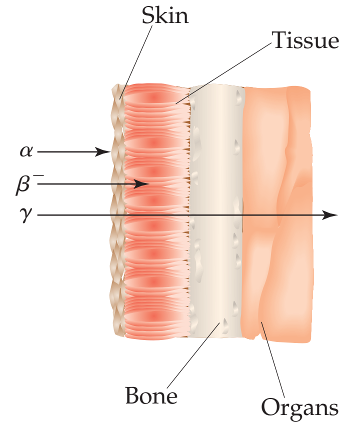
[‡] Includes lead-210 and polonium-210, daughter nuclei of uranium-238.

In general, the tissues damaged most by radiation are those that reproduce rapidly, such as bone marrow, blood-forming tissues, and lymph nodes. The principal effect of extended exposure to low doses of radiation is to cause cancer. Cancer is caused by damage to the growth-regulation mechanism of cells, inducing the cells to reproduce uncontrollably. Leukemia, which is characterized by excessive growth of white blood cells, is probably the major type of radiation-caused cancer.

In light of the biological effects of radiation, it is important to determine whether any levels of exposure are safe. Unfortunately, we are hampered in our attempts to set realistic standards because we do not fully understand the effects of long-term exposure. Scientists concerned with setting health standards have used the hypothesis that the effects of radiation are proportional to exposure. *Any* amount of radiation is assumed to cause some finite risk of injury, and the effects of high-dosage rates are extrapolated to those of lower ones. Other scientists believe, however, that there is a threshold below which there are no radiation risks. Until scientific evidence enables us to settle the matter with some confidence, it is safer to assume that even low levels of radiation present some danger.

Go Figure

Why are alpha rays much more dangerous when the source of radiation is located inside the body?



▲ **Figure 21.23 Relative penetrating abilities of alpha, beta, and gamma radiation.**

Radiation Doses

Two units are commonly used to measure exposure to radiation. The **gray** (Gy), the SI unit of absorbed dose, corresponds to the absorption of 1 J of energy per kilogram of tissue. The **rad** (*r*adiation *a*bsorbed *d*ose) corresponds to the absorption of 1×10^{-2} J of energy per kilogram of tissue. Thus, 1 Gy = 100 rad. The rad is the unit most often used in medicine.

Not all forms of radiation harm biological materials to the same extent even at the same level of exposure. For example, 1 rad of alpha radiation can produce more damage than 1 rad of beta radiation. To correct for these differences, the radiation dose is multiplied by a factor that measures the relative damage caused by the radiation. This multiplication factor is known as the *relative biological effectiveness*, *RBE*. The RBE is approximately 1 for gamma and beta radiation, and 10 for alpha radiation.

The exact value of the RBE varies with dose rate, total dose, and type of tissue affected. The product of the radiation dose in rads and the RBE of the radiation give the *effective dosage* in **rem** (*r*oentgen *e*quivalent for *m*an):

$$\text{Number of rem} = (\text{number of rad})(\text{RBE}) \qquad [21.32]$$

The SI unit for effective dose is the *sievert* (Sv), obtained by multiplying the RBE times the SI unit for radiation dose, the gray; because a gray is 100 times larger than a rad, 1 Sv = 100 rem. The rem is the unit of radiation damage usually used in medicine.

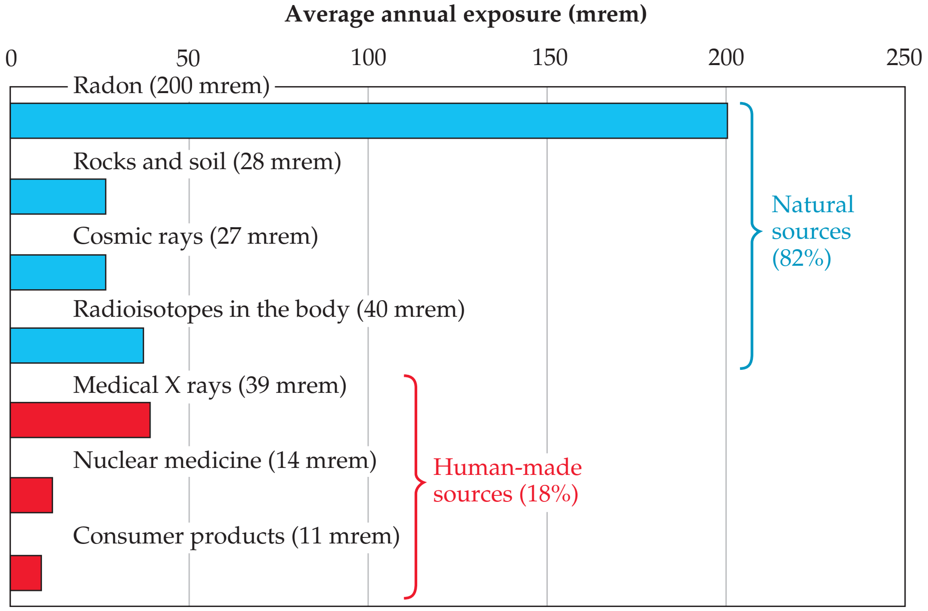
The effects of short-term exposure to radiation appear in **Table 21.9**. An exposure of 600 rem is fatal to most humans. To put this number in perspective, a typical dental X ray entails an exposure of about 0.5 mrem (that is, 0.0005 rem). The average exposure for a person in 1 yr due to all natural sources of ionizing radiation (called *background radiation*) is about 360 mrem (**Figure 21.24**).

Radon

Radon-222 is a product of the nuclear disintegration series of uranium-238 (Figure 21.2) and is continuously generated as uranium in rocks and soil decays. As Figure 21.24 indicates, radon exposure is estimated to account for more than half the 360-mrem average annual exposure to ionizing radiation.

TABLE 21.9 Effects of Short-Term Exposures to Radiation

Dose (rem)	Effect
0–25	No detectable clinical effects
25–50	Slight, temporary decrease in white blood cell counts
100–200	Nausea; marked decrease in white blood cell counts
500	Death of half the exposed population within 30 days



▲ **Figure 21.24 Sources of U.S. average annual exposure to high-energy radiation.** The total average annual exposure is 360 mrem.

Data from "Ionizing Radiation Exposure of the Population of the United States," Report 93, 1987 and Report 160, 2009, National Council on Radiation Protection.

The interplay between the chemical and nuclear properties of radon makes it a health hazard. Because radon is a noble gas, it is extremely unreactive and is therefore free to escape from the ground without chemically reacting along the way. It is readily inhaled and exhaled with no direct chemical effects. Its half-life, however, is only 3.82 days. It decays, by losing an alpha particle, into a radioisotope of polonium:

$$ {}^{222}_{86}\text{Rn} \longrightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\text{He} \qquad [21.33] $$

Because radon has such a short half-life and because alpha particles have a high RBE, inhaled radon is considered a probable cause of lung cancer. Even worse than the radon, however, is the decay product, because polonium-218 is an alpha-emitting chemically active element that has an even shorter half-life (3.11 min) than radon-222:

$$ {}^{218}_{84}\text{Po} \longrightarrow {}^{214}_{82}\text{Pb} + {}^{4}_{2}\text{He} \qquad [21.34] $$

When a person inhales radon, therefore, atoms of polonium-218 can become trapped in the lungs, where they bathe the delicate tissue with harmful alpha radiation. The resulting damage is estimated to contribute to 10% of all lung cancer deaths in the United States.

The U.S. Environmental Protection Agency (EPA) has recommended that radon-222 levels not exceed 4 pCi per liter of air in homes. Homes located in areas where the natural uranium content of the soil is high are particularly at high risk for radon levels much greater than that, and those areas have had significantly higher incidences of radon-induced lung cancer. In 2015, the EPA, in partnership with other organizations, launched the National Radon Action Plan, with the goal of reducing the radon risk for 5 million homes, mainly by increased testing and mitigation.

CHEMISTRY AND LIFE Radiation Therapy

Healthy cells are either destroyed or damaged by high-energy radiation, leading to physiological disorders. This radiation can also destroy *unhealthy* cells, however, including cancerous cells. All cancers are characterized by runaway cell growth that can produce *malignant tumors*. These tumors can be caused by the exposure of healthy cells to high-energy radiation. Paradoxically, however, they can be destroyed by the same radiation that caused them because the rapidly reproducing cells of the tumors are very susceptible to radiation damage. Thus, cancerous cells are more susceptible to destruction by radiation than healthy ones, allowing radiation to be used effectively in the treatment of cancer. As early as 1904, physicians used the radiation emitted by radioactive substances to treat tumors by destroying the mass of unhealthy tissue. The treatment of disease by high-energy radiation is called *radiation therapy*.

TABLE 21.10 Some Radioisotopes Used in Radiation Therapy

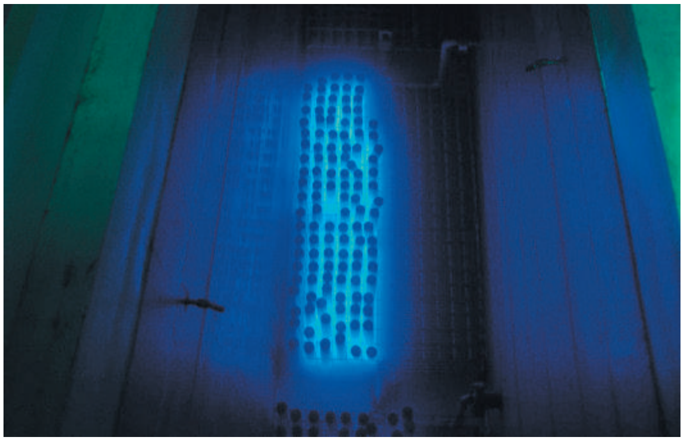
Isotope	Half-Life	Isotope	Half-Life
^{32}P	14.3 days	^{137}Cs	30 yr
^{60}Co	5.27 yr	^{192}Ir	74.2 days
^{90}Sr	28.8 yr	^{198}Au	2.7 days
^{125}I	60.25 days	^{222}Rn	3.82 days
^{131}I	8.04 days	^{226}Ra	1600 yr

Many radionuclides are currently used in radiation therapy. Some of the more commonly used ones are listed in **Table 21.10**. Most of them have short half-lives, meaning that they emit a great deal of radiation in a short period of time (**Figure 21.25**).

The radiation source used in radiation therapy may be inside or outside the body. In almost all cases, radiation therapy uses gamma radiation emitted by radioisotopes. Any alpha or beta radiation that is emitted concurrently can be blocked by appropriate packaging. For example, ^{192}Ir is often administered as "seeds" consisting of a core of radioactive isotope coated with 0.1 mm of platinum metal. The platinum coating stops the alpha and beta rays, but the gamma rays penetrate it readily. The radioactive seeds can be surgically implanted in a tumor.

In some cases, human physiology allows a radioisotope to be ingested. For example, most of the iodine in the human body ends up in the thyroid gland, so thyroid cancer can be treated by using large doses of ^{131}I. Radiation therapy on deep organs, where a surgical implant is impractical, often uses a ^{60}Co "gun" outside the body to shoot a beam of gamma rays at the tumor. Particle accelerators are also used as an external source of high-energy radiation for radiation therapy.

Because gamma radiation is so strongly penetrating, it is nearly impossible to avoid damaging healthy cells during radiation therapy. Many cancer patients undergoing radiation treatment experience unpleasant and dangerous side effects, such as fatigue, nausea, hair loss, a weakened immune system, and occasionally even death. However, if other treatments such as *chemotherapy* (the use of drugs to combat cancer) fail, radiation therapy can be a good option.



▲ **Figure 21.25 Storage of radioactive cesium.** The vials contain a salt of cesium-137, a beta emitter that is both a waste product of nuclear fission and used in radiation therapy. The blue glow is from the radioactivity of the cesium.

Much current research in radiation therapy is engaged in developing new drugs that specifically target tumors using a method called *neutron capture therapy*. In this technique, a nonradioactive isotope, usually boron-10, is concentrated in the tumor by using specific tumor-seeking reagents. The boron-10 is then irradiated with neutrons, where it undergoes the following nuclear reaction, producing alpha particles:

$$^{10}_{5}B + ^{1}_{0}n \longrightarrow ^{7}_{3}Li + ^{4}_{2}He$$

Tumor cells are killed or damaged by exposure to the alpha particles. Healthy tissue farther away from the tumor is unaffected because of the short-range penetrating power of alpha particles. Thus, neutron-capture therapy holds promise as a "silver bullet" that specifically targets unhealthy cells for exposure to radiation.

Self-Assessment Exercises

SAE 21.20 Why is ionizing radiation more harmful to biological systems than nonionizing radiation? (**a**) Ionizing radiation tends not to have enough energy to have an effect on biological systems. (**b**) Ionizing radiation is generally lower in energy and does not ionize water. (**c**) Ionizing radiation removes electrons from water molecules and forms damaging free radicals. (**d**) Ionizing radiation does not cause tissue damage or cancer.

SAE 21.21 If a 75-kg man is irradiated uniformly by 0.15-J alpha radiation, what is the effective dosage in rem? (**a**) 0.00020 rem (**b**) 0.0020 rem (**c**) 0.20 rem (**d**) 2.0 rem

Putting Concepts Together

Potassium ion is present in foods and is an essential nutrient in the human body. One of the naturally occurring isotopes of potassium, potassium-40, is radioactive. Potassium-40 has a natural abundance of 0.0117% and a half-life of $t_{1/2} = 1.28 \times 10^9$ yr. It undergoes radioactive decay in three ways: 98.2% is by electron capture, 1.35% is by beta emission, and 0.49% is by positron emission. (**a**) Why should we expect ^{40}K to be radioactive? (**b**) Write the nuclear equations for the three modes by which ^{40}K decays. (**c**) How many $^{40}K^+$ ions are present in 1.00 g of KCl? (**d**) How long does it take for 1.00% of the ^{40}K in a sample to undergo radioactive decay?

Continued

SOLUTION

(a) The ^{40}K nucleus contains 19 protons and 21 neutrons. There are very few stable nuclei with odd numbers of both protons and neutrons (Section 21.2).

(b) Electron capture is capture of an inner-shell electron by the nucleus:

$$^{40}_{19}\text{K} + {}^{0}_{-1}\text{e} \longrightarrow {}^{40}_{18}\text{Ar}$$

Beta emission is loss of a beta particle (${}^{0}_{-1}\text{e}$) by the nucleus:

$$^{40}_{19}\text{K} \longrightarrow {}^{40}_{20}\text{Ca} + {}^{0}_{-1}\text{e}$$

Positron emission is loss of a positron (${}^{0}_{+1}\text{e}$) by the nucleus:

$$^{40}_{19}\text{K} \longrightarrow {}^{40}_{18}\text{Ar} + {}^{0}_{+1}\text{e}$$

(c) The total number of K^+ ions in the sample is:

$$(1.00\ \cancel{\text{g KCl}})\left(\frac{1\ \cancel{\text{mol KCl}}}{74.55\ \cancel{\text{g KCl}}}\right)\left(\frac{1\ \cancel{\text{mol K}^+}}{1\ \cancel{\text{mol KCl}}}\right)\left(\frac{6.022\times10^{23}\ \text{K}^+}{1\ \cancel{\text{mol K}^+}}\right) = 8.08\times10^{21}\ \text{K}^+\ \text{ions}$$

Of these, 0.0117% are $^{40}\text{K}^+$ ions:

$$(8.08\times10^{21}\ \cancel{\text{K}^+\ \text{ions}})\left(\frac{0.0117\ {}^{40}\text{K}^+\ \text{ions}}{100\ \cancel{\text{K}^+\ \text{ions}}}\right) = 9.45\times10^{17}\ {}^{40}\text{K}^+\ \text{ions}$$

(d) The decay constant (the rate constant) for the radioactive decay can be calculated from the half-life, using Equation 21.19:

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.28\times10^{9}\ \text{yr}} = (5.41\times10^{-10})/\text{yr}$$

The rate equation, Equation 21.20, then allows us to calculate the time required:

$$\ln\frac{N_t}{N_0} = -kt$$

$$\ln\frac{99}{100} = -[(5.41\times10^{-10})/\text{yr}]t$$

$$-0.01005 = -[(5.41\times10^{-10})/\text{yr}]t$$

$$t = \frac{-0.01005}{(-5.41\times10^{-10})/\text{yr}} = 1.86\times10^{7}\ \text{yr}$$

That is, it would take 18.6 million years for just 1.00% of the ^{40}K in a sample to decay.

Chapter Summary and Key Terms

RADIOACTIVITY AND NUCLEAR EQUATIONS (SECTION 21.1) The nucleus of an atom contains protons and neutrons, both of which are called **nucleons**. Reactions that involve changes in atomic nuclei are called **nuclear reactions**. Nuclei that spontaneously change by emitting radiation are said to be **radioactive**. Radioactive nuclei are called **radionuclides**, and the atoms containing them are called **radioisotopes**. Radionuclides spontaneously change through a process called radioactive decay. The three most important types of radiation given off as a result of radioactive decay are **alpha (α) particles** (${}^{4}_{2}\text{He}$ or α), **beta (β) particles** (${}^{0}_{-1}\text{e}$ or β^-), and **gamma (γ) radiation** (${}^{0}_{0}\gamma$ or γ). **Positrons** (${}^{0}_{+1}\text{e}$ or β^+), which are particles with the same mass as an electron but the opposite charge, can also be produced when a radioisotope decays.

In nuclear equations, reactant and product nuclei are represented by giving their mass numbers and atomic numbers, as well as their chemical symbol. The totals of the mass numbers on both sides of the equation are equal; the totals of the atomic numbers on both sides are also equal. There are four common modes of radioactive decay: **alpha emission**, which reduces the atomic number by 2 and the mass number by 4; **beta emission**, which increases the atomic number by 1 and leaves the mass number unchanged; and **positron emission** and **electron capture**, both of which reduce the atomic number by 1 and leave the mass number unchanged.

PATTERNS OF NUCLEAR STABILITY (SECTION 21.2) The neutron-to-proton ratio is an important factor determining nuclear stability. By comparing a nuclide's neutron-to-proton ratio with those of stable nuclei, we can predict the mode of radioactive decay. In general, neutron-rich nuclei tend to emit beta particles; proton-rich nuclei tend to either emit positrons or undergo electron capture; and heavy nuclei tend to emit alpha particles. The presence of **magic numbers** of nucleons and an even number of protons and neutrons also help determine the stability of a nucleus. A nuclide may undergo a series of decay steps before a stable nuclide forms. This series of steps is called a **radioactive decay chain** or a **nuclear disintegration series**.

NUCLEAR TRANSMUTATIONS (SECTION 21.3) **Nuclear transmutations**, induced conversions of one nucleus into another, can be brought about by bombarding nuclei with either charged particles or neutrons. **Particle accelerators** increase the kinetic energies of positively charged particles, allowing these particles to overcome their electrostatic repulsion by the nucleus. Nuclear transmutations are used to produce the **transuranium elements**—those elements with atomic numbers greater than that of uranium.

RADIOACTIVE DECAY RATES AND DETECTION OF RADIOACTIVITY (SECTIONS 21.4 AND 21.5) The SI unit for the activity of a radioactive source is the **becquerel** (Bq), defined as one nuclear disintegration per second. A related unit, the **curie** (Ci), corresponds to 3.7×10^{10} disintegrations per second. Nuclear decay is a first-order process. The decay rate (**activity**) is therefore directly proportional to the number of radioactive nuclei. The **half-life** of a radionuclide, which is a constant independent of temperature, is the time needed for one-half of the nuclei to decay. Some radioisotopes can be used to date objects; ^{14}C, for example, is used to date organic objects. Geiger counters and scintillation counters count the emissions from radioactive samples. The ease of detection of radioisotopes also permits their use as **radiotracers** to follow elements through reactions.

ENERGY CHANGES IN NUCLEAR REACTIONS (SECTION 21.6) The energy produced in nuclear reactions is accompanied by measurable changes of mass in accordance with Einstein's relationship, $\Delta E = c^2 \Delta m$. The difference in mass between nuclei and the nucleons of which they are composed is known as the **mass defect**. The mass defect of a nuclide makes it possible to calculate its **nuclear binding energy**, the energy required to separate the nucleus into individual nucleons. Because of trends in the nuclear binding energy with atomic number, energy is produced when heavy nuclei split (**fission**) and when light nuclei fuse (**fusion**).

NUCLEAR FISSION AND NUCLEAR FUSION (SECTIONS 21.7 AND 21.8) Uranium-235, uranium-233, and plutonium-239 undergo fission when they capture a neutron, splitting into lighter nuclei and releasing more neutrons. The neutrons produced in one fission can cause further fission reactions, which can lead to a nuclear **chain reaction**. A reaction that maintains a constant rate is said to be critical, and the mass necessary to maintain this constant rate is called a **critical mass**. A mass in excess of the critical mass is termed a **supercritical mass**.

In nuclear reactors, the fission rate is controlled to generate a constant power. The reactor core consists of fuel elements containing fissionable nuclei, control rods, a moderator, and a primary coolant. A nuclear power plant resembles a conventional power plant except that the reactor core replaces the fuel burner. There is concern about the disposal of highly radioactive nuclear wastes that are generated in nuclear power plants.

Nuclear fusion requires high temperatures because nuclei must have large kinetic energies to overcome their mutual repulsions. Fusion reactions are therefore called **thermonuclear reactions**. It is not yet possible to generate power on Earth through a controlled fusion process.

RADIATION IN THE ENVIRONMENT AND LIVING SYSTEMS (SECTION 21.9) **Ionizing radiation** is energetic enough to remove an electron from a water molecule; radiation with less energy is called **nonionizing radiation**. Ionizing radiation generates **free radicals**, reactive substances with one or more unpaired electrons. The effects of long-term exposure to low levels of radiation are not completely understood, but there is evidence that the extent of biological damage varies in direct proportion to the level of exposure.

The amount of energy deposited in biological tissue by radiation is called the radiation dose and is measured in units of gray or rad. One **gray** (Gy) corresponds to a dose of 1 J/kg of tissue. It is the SI unit of radiation dose. The **rad** is a smaller unit; 100 rad = 1 Gy. The effective dose, which measures the biological damage created by the deposited energy, is measured in units of rem or sievert (Sv). The **rem** is obtained by multiplying the number of rad by the relative biological effectiveness (RBE); 100 rem = 1 Sv.

Key Equations

• $k = \dfrac{0.693}{t_{1/2}}$	[21.19]	Relationship between nuclear decay constant and half-life; this is derived from the following equation at $N_t = \frac{1}{2}N_0$
• $\ln\dfrac{N_t}{N_0} = -kt$	[21.20]	First-order rate law for nuclear decay
• $E = mc^2$	[21.22]	Einstein's equation that relates mass and energy

Exam Prep

EP 21.1 What product forms when plutonium-238 undergoes alpha emission? (**a**) plutonium-234 (**b**) uranium-234 (**c**) uranium-238 (**d**) thorium-236 (**e**) neptunium-237

EP 21.2 Which of the following statements is or are *true*?

(**i**) Gamma radiation is more penetrating than alpha radiation.
(**ii**) Alpha radiation consists of a stream of helium-4 nuclei.
(**iii**) When a nuclide undergoes beta emission, both the atomic number and the mass number are changed.

(**a**) Only statement i is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 21.3 The radioactive decay of thorium-232 occurs in multiple steps, called a *radioactive decay chain*. The second product produced in this chain is actinium-228. Which of the following processes could lead to this product starting with thorium-232?

(**a**) alpha decay followed by beta emission
(**b**) beta emission followed by electron capture
(**c**) positron emission followed by alpha decay
(**d**) electron capture followed by positron emission
(**e**) More than one of the above is consistent with the observed transformation.

EP 21.4 Iron-55 undergoes radioactive decay by electron capture. What is the product of this decay process?

(**a**) chromium-51
(**b**) cobalt-55
(**c**) iron-56
(**d**) manganese-55

EP 21.5 Which of the following nuclides would you expect to be radioactive?

(**a**) $^{90}_{40}Zr$
(**b**) $^{134}_{55}Cs$
(**c**) $^{140}_{58}Ce$
(**d**) $^{208}_{82}Pb$

EP 21.6 Which of the following radioactive nuclei is most likely to decay via emission of a β^- particle?

(**a**) nitrogen-13
(**b**) magnesium-23
(**c**) rubidium-83
(**d**) iodine-131
(**e**) neptunium-237

EP 21.7 What is the identity of nucleus X in the following nuclear transmutation? $^{238}_{92}U(n, \beta^-)X$.

(**a**) $^{238}_{93}Np$
(**b**) $^{239}_{92}U$
(**c**) $^{239}_{92}U^+$
(**d**) $^{235}_{90}Th$
(**e**) $^{239}_{93}Np$

EP 21.8 A radioisotope of technetium is useful in medical imaging techniques. A sample initially contains 80.0 mg of this isotope. After 24.0 h, only 5.0 mg of the technetium isotope remains. What is the half-life of the isotope?

(a) 3.0 h
(b) 6.0 h
(c) 12.0 h
(d) 16.0 h
(e) 24.0 h

EP 21.9 Cesium-137, which has a half-life of 30.2 yr, is a component of the radioactive waste from nuclear power plants. If the activity due to cesium-137 in a sample of radioactive waste has decreased to 35.2% of its initial value, how old is the sample?

(a) 1.04 yr
(b) 15.4 yr
(c) 31.5 yr
(d) 45.5 yr
(e) 156 yr

EP 21.10 A team of archeologists recover a plank of wood believed to be from an ancient ship. The plank has a carbon-14 activity of 35.8 Bq per gram of carbon. In comparison, a living organism has a C-14 activity of 47.5 Bq per gram of carbon. If the half-life of carbon-14 is 5730 years, what is the age of the plank?

(a) 1020 yr
(b) 1620 yr
(c) 2340 yr
(d) 11,000 yr

EP 21.11 Electricity is generated in space vehicles from the heat produced by the radioactive decay of plutonium-238: ${}^{238}_{94}\text{Pu} \longrightarrow {}^{234}_{92}\text{U} + {}^{4}_{2}\text{He}$. The atomic masses of plutonium-238 and uranium-234 are 238.049554 amu and 234.040946 amu, respectively. The mass of an alpha particle is 4.001506 amu. How much energy in kJ is released when 1.00 g of plutonium-238 decays to uranium-234?

(a) 2.27×10^6 kJ
(b) 2.68×10^6 kJ
(c) 3.10×10^6 kJ
(d) 3.15×10^6 kJ
(e) 7.37×10^8 kJ

EP 21.12 The mass of a magnesium-25 nucleus is 24.98584 amu. What is the binding energy of this nucleus? The mass of a neutron is 1.008664916 amu, the mass of a proton is 1.007276466 amu, the speed of light is 2.9979×10^8 m/s, and 1 amu = $1.660538921 \times 10^{-27}$ kg.

(a) $3.72887048 \times 10^{-9}$ J
(b) $6.24499767 \times 10^{-9}$ J
(c) $3.19553534 \times 10^{-11}$ J
(d) $2.92616053 \times 10^{-11}$ J

EP 21.13 Identify the missing product in the following nuclear fission reaction:

$${}^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{90}_{38}\text{Sr} + \underline{\quad\quad} + 2\,{}^{1}_{0}\text{n}$$

(a) ${}^{144}_{54}\text{Xe}$
(b) ${}^{142}_{54}\text{Xe}$
(c) ${}^{145}_{54}\text{Xe}$
(d) ${}^{144}_{52}\text{Te}$

EP 21.14 Which of the following statements about nuclear fission and fusion is or are *true*?

(i) Nuclear fission is a favorable process for very heavy nuclei.
(ii) Nuclear fusion occurs between very light nuclei.
(iii) In both nuclear fission and nuclear fusion, the energy released is a consequence of the variation of nuclear binding energies among the elements.

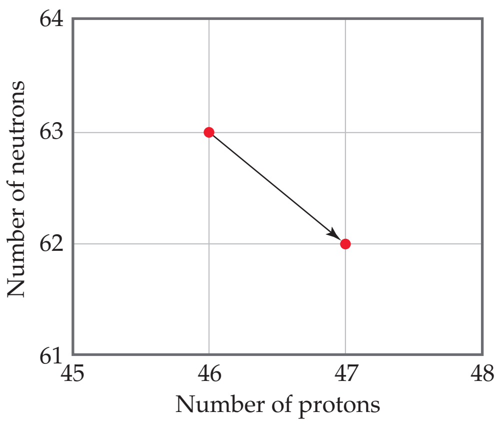
(a) Only one of the statements is true. **(b)** Statements i and ii are true. **(c)** Statements i and iii are true. **(d)** Statements ii and iii are true. **(e)** All three statements are true.

Exercises

Visualizing Concepts

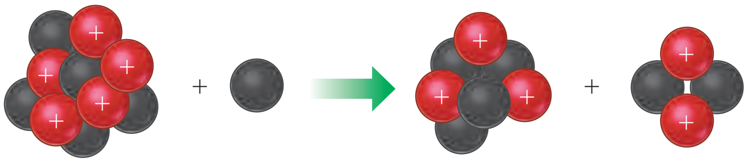
21.1 Indicate whether each of the following nuclides lies within the belt of stability in Figure 21.2: **(a)** neon-24, **(b)** chlorine-32, **(c)** tin-108, **(d)** polonium-216. For any that do not, describe a nuclear decay process that would alter the neutron-to-proton ratio in the direction of increased stability. [Section 21.2]

21.2 Write the balanced nuclear equation for the reaction represented by the diagram shown here. [Section 21.2]

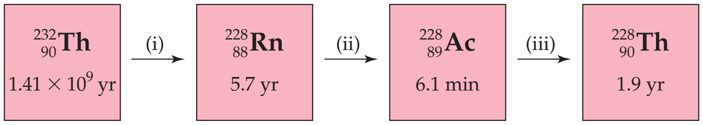


21.3 Draw a diagram similar to that shown in Exercise 21.2 that illustrates the nuclear reaction ${}^{211}_{83}\text{Bi} \longrightarrow {}^{4}_{2}\text{He} + {}^{207}_{81}\text{Tl}$. [Section 21.2]

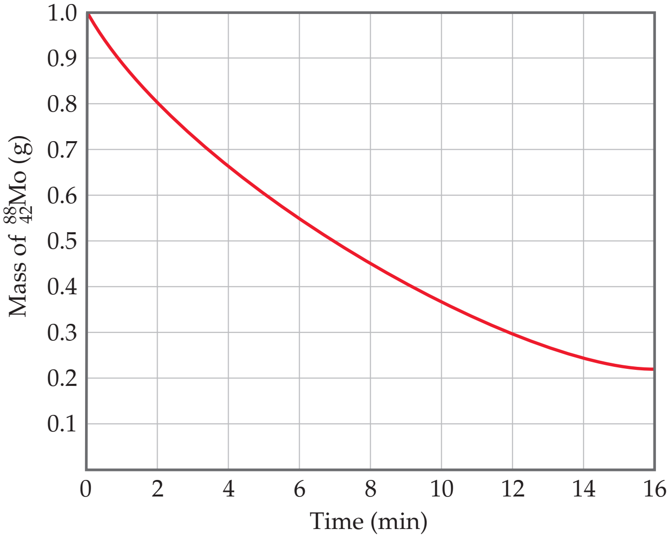
21.4 In the sketch shown here, the red spheres represent protons and the gray spheres represent neutrons. **(a)** What are the identities of the four particles involved in the reaction depicted? **(b)** Write the transformation represented below using condensed notation. **(c)** Based on its atomic number and mass number, do you think the product nucleus is stable or radioactive? [Section 21.3]



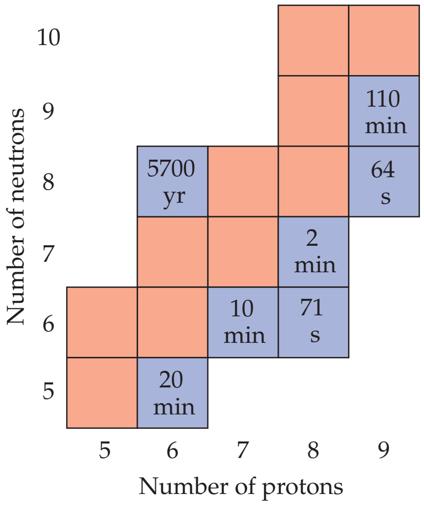
21.5 The diagram shows three of the steps in the radioactive decay chain for ${}^{232}_{90}\text{Th}$. The half-life of each isotope is shown below the symbol of the isotope. **(a)** Identify the type of radioactive decay for each of the steps (i), (ii), and (iii). **(b)** Which of the isotopes shown has the highest activity? **(c)** Which of the isotopes shown has the lowest activity? **(d)** The next step in the decay chain is an alpha emission. What is the next isotope in the chain? [Sections 21.2 and 21.4]



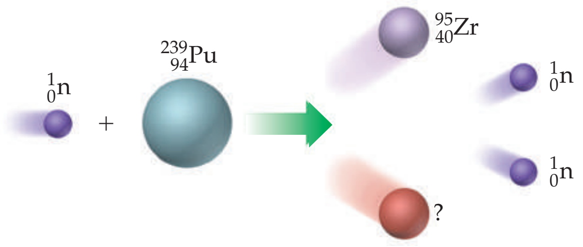
21.6 The accompanying graph illustrates the decay of ${}^{88}_{42}\text{Mo}$, which decays via positron emission. **(a)** What is the half-life of the decay? **(b)** What is the rate constant for the decay? **(c)** What fraction of the original sample of ${}^{88}_{42}\text{Mo}$ remains after 12 min? (**d**) What is the product of the decay process? [Section 21.4]



21.7 All the stable isotopes of boron, carbon, nitrogen, oxygen, and fluorine are shown in the accompanying chart (in red), along with their radioactive isotopes with $t_{1/2} > 1$ min (in blue). (**a**) Write the chemical symbols, including mass and atomic numbers, for all of the stable isotopes. (**b**) Which radioactive isotopes are most likely to decay by beta emission? (**c**) Some of the isotopes shown are used in positron emission tomography. Which ones would you expect to be most useful for this application? (**d**) Which isotope would decay to 12.5% of its original concentration after 1 hour? [Sections 21.2, 21.4, and 21.5]



21.8 The diagram shown here illustrates a fission process. (**a**) What is the unidentified product of the fission? (**b**) Use Figure 21.2 to predict whether the nuclear products of this fission reaction are stable. [Section 21.7]



Radioactivity and Nuclear Equations (Section 21.1)

21.9 Indicate the number of protons and neutrons in the following nuclei: (**a**) $^{56}_{24}$Cr, (**b**) ^{193}Tl, (**c**) argon-38.

21.10 Indicate the number of protons and neutrons in the following nuclei: (**a**) $^{129}_{53}$I, (**b**) ^{138}Ba, (**c**) neptunium-237.

21.11 Give the symbol for (**a**) a neutron, (**b**) an alpha particle, (**c**) gamma radiation.

21.12 Give the symbol for (**a**) a proton, (**b**) a beta particle, (**c**) a positron.

21.13 Write balanced nuclear equations for the following processes: (**a**) rubidium-90 undergoes beta emission; (**b**) selenium-72 undergoes electron capture; (**c**) krypton-76 undergoes positron emission; (**d**) radium-226 emits alpha radiation.

21.14 Write balanced nuclear equations for the following transformations: (**a**) bismuth-213 undergoes alpha decay; (**b**) nitrogen-13 undergoes electron capture; (**c**) technicium-98 undergoes electron capture; (**d**) gold-188 decays by positron emission.

21.15 Decay of which nucleus will lead to the following products? (**a**) bismuth-211 by beta decay (**b**) chromium-50 by positron emission (**c**) tantalum-179 by electron capture (**d**) radium-226 by alpha decay

21.16 What particle is produced during the following decay processes? (**a**) Sodium-24 decays to magnesium-24. (**b**) Mercury-188 decays to gold-188. (**c**) Iodine-122 decays to xenon-122. (**d**) Plutonium-242 decays to uranium-238.

21.17 The naturally occurring radioactive decay series that begins with $^{235}_{92}$U stops with formation of the stable $^{207}_{82}$Pb nucleus. The decays proceed through a series of alpha-particle and beta-particle emissions. How many of each type of emission are involved in this series?

21.18 A radioactive decay series that begins with $^{232}_{90}$Th ends with formation of the stable nuclide $^{208}_{82}$Pb. How many alpha-particle emissions and how many beta-particle emissions are involved in the sequence of radioactive decays?

Patterns of Nuclear Stability (Section 21.2)

21.19 Predict the type of radioactive decay process for the following radionuclides: (**a**) $^{8}_{5}$B, (**b**) $^{68}_{29}$Cu, (**c**) phosphorus-32, (**d**) chlorine-39.

21.20 Each of the following nuclei undergoes either beta decay or positron emission. Predict the type of emission for each: (**a**) tritium, $^{3}_{1}$H, (**b**) $^{89}_{38}$Sr, (**c**) iodine-120, (**d**) silver-102.

21.21 One of the nuclides in each of the following pairs is radioactive. Predict which is radioactive and which is stable: (**a**) $^{39}_{19}$K and $^{40}_{19}$K, (**b**) ^{209}Bi and ^{208}Bi, (**c**) nickel-58 and nickel-65.

21.22 One nuclide in each of these pairs is radioactive. Predict which is radioactive and which is stable: (**a**) $^{40}_{20}$Ca and $^{45}_{20}$Ca, (**b**) ^{12}C and ^{14}C, (**c**) lead-206 and thorium-230. Explain your choice in each case.

21.23 Which of the following nuclides have magic numbers of both protons and neutrons? (**a**) helium-4 (**b**) oxygen-18 (**c**) calcium-40 (**d**) zinc-66 (**e**) lead-208

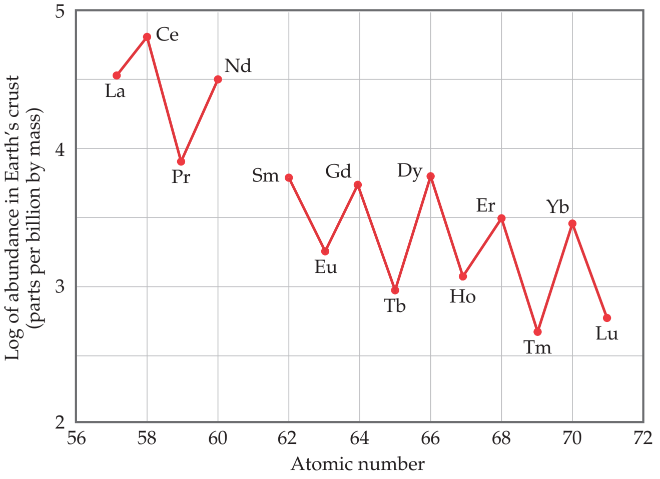
21.24 Despite the similarities in the chemical reactivity of elements in the lanthanide series, their abundance in Earth's crust varies by two orders of magnitude. This graph shows the relative abundance as a function of atomic number. Which of the following statements best explains the sawtooth variation across the series?

(**a**) The elements with an odd atomic number lie above the belt of stability.

(**b**) The elements with an odd atomic number lie below the belt of stability.

(c) The elements with an even atomic number have a magic number of protons.

(d) Pairs of protons have a special stability.



21.25 Which of the following statements best explains why alpha emission is relatively common, but proton emission is extremely rare?

(a) Alpha particles are very stable due to magic numbers of protons and neutrons.

(b) Alpha particles occur in the nucleus.

(c) Alpha particles are the nuclei of an inert gas.

(d) An alpha particle has a higher charge than a proton.

21.26 Which of the following nuclides would you expect to be radioactive: ${}^{58}_{26}\text{Fe}$, ${}^{60}_{27}\text{Co}$, ${}^{92}_{41}\text{Nb}$, mercury-202, radium-226? Justify your choices.

Nuclear Transmutations (Section 21.3)

21.27 Which statement best explains why nuclear transmutations involving neutrons are generally easier to accomplish than those involving protons or alpha particles?

(a) Neutrons are not a magic number particle.

(b) Neutrons do not have an electrical charge.

(c) Neutrons are smaller than protons or alpha particles.

(d) Neutrons are attracted to the nucleus even at long distances, whereas protons and alpha particles are repelled.

21.28 In 1930, the American physicist Ernest Lawrence designed the first cyclotron in Berkeley, California. In 1937 Lawrence bombarded a molybdenum target with deuterium ions, producing for the first time an element not found in nature. What was this element? Starting with molybdenum-96 as your reactant, write a nuclear equation to represent this process.

21.29 Complete and balance the following nuclear equations by supplying the missing particle:

(a) ${}^{252}_{98}\text{Cf} + {}^{10}_{5}\text{B} \longrightarrow 3\,{}^{1}_{0}\text{n} + ?$

(b) ${}^{2}_{1}\text{H} + {}^{3}_{2}\text{He} \longrightarrow {}^{4}_{2}\text{He} + ?$

(c) ${}^{1}_{1}\text{H} + {}^{11}_{5}\text{B} \longrightarrow 3\,?$

(d) ${}^{122}_{53}\text{I} \longrightarrow {}^{122}_{54}\text{Xe} + ?$

(e) ${}^{59}_{26}\text{Fe} \longrightarrow {}^{0}_{-1}\text{e} + ?$

21.30 Complete and balance the following nuclear equations by supplying the missing particle:

(a) ${}^{14}_{7}\text{N} + {}^{4}_{2}\text{He} \longrightarrow ? + {}^{1}_{1}\text{H}$

(b) ${}^{40}_{19}\text{K} + {}^{0}_{-1}\text{e}$ (orbital electron) $\longrightarrow ?$

(c) $? + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{14}\text{Si} + {}^{1}_{1}\text{H}$

(d) ${}^{58}_{26}\text{Fe} + 2\,{}^{1}_{0}\text{n} \longrightarrow {}^{60}_{27}\text{Co} + ?$

(e) ${}^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{135}_{54}\text{Xe} + 2\,{}^{1}_{0}\text{n} + ?$

21.31 Write balanced equations for **(a)** ${}^{238}_{92}\text{U}(\alpha, \text{n}){}^{241}_{94}\text{Pu}$, **(b)** ${}^{14}_{7}\text{N}(\alpha, \text{p}){}^{17}_{8}\text{O}$, **(c)** ${}^{56}_{26}\text{Fe}(\alpha, \beta^-){}^{60}_{29}\text{Cu}$.

21.32 Write balanced equations for each of the following nuclear reactions: **(a)** ${}^{238}_{92}\text{U}(\text{n}, \gamma){}^{239}_{92}\text{U}$, **(b)** ${}^{16}_{8}\text{O}(\text{p}, \alpha){}^{13}_{7}\text{N}$, **(c)** ${}^{18}_{8}\text{O}(\text{n}, \beta^-){}^{19}_{9}\text{F}$.

Rates of Radioactive Decay (Section 21.4)

21.33 Which of the following statements about the half-lives of radionuclides are *true*?

(a) As the half-life increases, the decay rate constant decreases.

(b) After two half-lives, a sample of a radionuclide will have decreased to 1/4 of its original size.

(c) The half-life is a measure of the type of radiation emitted by the radionuclide.

21.34 It has been suggested that strontium-90 (generated by nuclear testing) deposited in the hot desert will undergo radioactive decay more rapidly because it will be exposed to much higher average temperatures. **(a)** Is this a reasonable suggestion? **(b)** Does the process of radioactive decay have an activation energy, like the Arrhenius behavior of many chemical reactions? (Section 14.4)

21.35 Some watch dials are coated with a phosphor, like ZnS, and a polymer in which some of the ${}^{1}\text{H}$ atoms have been replaced by ${}^{3}\text{H}$ atoms (tritium). The phosphor emits light when struck by the beta particle from the tritium decay, causing the dials to glow in the dark. The half-life of tritium is 12.3 yr. If the light given off is assumed to be directly proportional to the amount of tritium, by how much will a dial be dimmed in a watch that is 50 yr old?

21.36 It takes 4 h 39 min for a 2.00-mg sample of radium-230 to decay to 0.25 mg. What is the half-life of radium-230?

21.37 Cobalt-60 is a strong gamma emitter that has a half-life of 5.26 yr. The cobalt-60 in a radiotherapy unit must be replaced when its radioactivity falls to 75% of the original sample. If an original sample was purchased in June 2021, when will it be necessary to replace the cobalt-60?

21.38 How much time is required for a 6.25-mg sample of ${}^{51}\text{Cr}$ to decay to 0.75 mg if it has a half-life of 27.8 days?

21.39 Radium-226, which undergoes alpha decay, has a half-life of 1600 yr. **(a)** How many alpha particles are emitted in 5.0 min by a 10.0-mg sample of ${}^{226}\text{Ra}$? **(b)** What is the activity of the sample in mCi?

21.40 Cobalt-60, which undergoes beta decay, has a half-life of 5.26 yr. **(a)** How many beta particles are emitted in 600 s by a 3.75-mg sample of ${}^{60}\text{Co}$? **(b)** What is the activity of the sample in Bq?

21.41 The cloth shroud from around a mummy is found to have a ${}^{14}\text{C}$ activity of 9.7 disintegrations per minute per gram of carbon as compared with living organisms that undergo 16.3 disintegrations per minute per gram of carbon. From the half-life for ${}^{14}\text{C}$ decay, 5730 yr, calculate the age of the shroud.

21.42 A wooden artifact from a Chinese temple has a ${}^{14}\text{C}$ activity of 38.0 counts per minute as compared with an activity of 58.2 counts per minute for a standard of zero age. From the half-life for ${}^{14}\text{C}$ decay, 5730 yr, determine the age of the artifact.

21.43 Potassium-40 decays to argon-40 with a half-life of 1.27×10^9 yr. What is the age of a rock in which the mass ratio of ${}^{40}\text{Ar}$ to ${}^{40}\text{K}$ is 4.2?

21.44 The half-life for the process ${}^{238}\text{U} \longrightarrow {}^{206}\text{Pb}$ is 4.5×10^9 yr. A mineral sample contains 75.0 mg of ${}^{238}\text{U}$ and 18.0 mg of ${}^{206}\text{Pb}$. What is the age of the mineral?

Energy Changes in Nuclear Reactions (Section 21.6)

21.45 An analytical laboratory balance typically measures mass to the nearest 0.1 mg. What energy change would accompany the loss of 0.1 mg in mass?

21.46 The thermite reaction, $\text{Fe}_2\text{O}_3(s) + 2\,\text{Al}(s) \longrightarrow 2\,\text{Fe}(s) + \text{Al}_2\text{O}_3(s)$, $\Delta H^\circ = -851.5$ kJ/mol, is one of the most exothermic reactions known. Because the heat released is sufficient to melt the iron product, the reaction is used to weld metal under the ocean. How much heat is released per mole of Al_2O_3 produced? How does this amount of thermal energy compare with the energy released when 2 mol of protons and 2 mol of neutrons combine to form 1 mol of alpha particles?

21.47 How much energy must be supplied to break a single aluminum-27 nucleus into separated protons and neutrons if an aluminum-27 atom has a mass of 26.9815386 amu? How much energy is required for 100.0 g of aluminum-27? (The mass of an electron is given on the inside back cover.)

21.48 How much energy must be supplied to break a single ${}^{21}\text{Ne}$ nucleus into separated protons and neutrons if the nucleus has a mass of 20.98846 amu? What is the nuclear binding energy for 1 mol of ${}^{21}\text{Ne}$?

21.49 The atomic masses of hydrogen-2 (deuterium), helium-4, and lithium-6 are 2.014102 amu, 4.002602 amu, and 6.0151228 amu, respectively. For each isotope, calculate (**a**) the nuclear mass, (**b**) the nuclear binding energy, (**c**) the nuclear binding energy per nucleon. (**d**) Which of these three isotopes has the largest nuclear binding energy per nucleon? Does this agree with the trends plotted in Figure 21.12?

21.50 The atomic masses of nitrogen-14, titanium-48, and xenon-129 are 13.999234 amu, 47.935878 amu, and 128.904779 amu, respectively. For each isotope, calculate (**a**) the nuclear mass, (**b**) the nuclear binding energy, (**c**) the nuclear binding energy per nucleon.

21.51 The energy from solar radiation falling on Earth is 1.07×10^{16} kJ/min. (**a**) How much loss of mass from the Sun occurs in one day from just the energy falling on Earth? (**b**) If the energy released in the reaction

$$ {}^{235}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{141}_{56}\text{Ba} + {}^{92}_{36}\text{Kr} + 3\,{}^{1}_{0}\text{n} $$

(${}^{235}\text{U}$ nuclear mass, 234.9935 amu; ${}^{141}\text{Ba}$ nuclear mass, 140.8833 amu; ${}^{92}\text{Kr}$ nuclear mass, 91.9021 amu) is taken to be typical of that occurring in a nuclear reactor, what mass of uranium-235 is required to equal 0.10% of the solar energy that falls on Earth in 1.0 day?

21.52 Based on the following atomic mass values—${}^{1}\text{H}$, 1.00782 amu; ${}^{2}\text{H}$, 2.01410 amu; ${}^{3}\text{H}$, 3.01605 amu; ${}^{3}\text{He}$, 3.01603 amu; ${}^{4}\text{He}$, 4.00260 amu—and the mass of the neutron given in the text, calculate the energy released per mole in each of the following nuclear reactions, all of which are possibilities for a controlled fusion process:

(**a**) ${}^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \longrightarrow {}^{4}_{2}\text{He} + {}^{1}_{0}\text{n}$

(**b**) ${}^{2}_{1}\text{H} + {}^{2}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{1}_{0}\text{n}$

(**c**) ${}^{2}_{1}\text{H} + {}^{3}_{2}\text{He} \longrightarrow {}^{4}_{2}\text{He} + {}^{1}_{1}\text{H}$

21.53 Using Figure 21.12, predict which of the following nuclei are likely to have the largest mass defect per nucleon: (**a**) ${}^{11}\text{B}$, (**b**) ${}^{51}\text{V}$, (**c**) ${}^{118}\text{Sn}$, (**d**) ${}^{243}\text{Cm}$.

21.54 The isotope ${}^{62}_{28}\text{Ni}$ has the largest binding energy per nucleon of any isotope. Calculate this value from the atomic mass of nickel-62 (61.928345 amu) and compare it with the value given for iron-56 in Table 21.7.

Nuclear Power and Radioisotopes (Sections 21.7, 21.8, and 21.9)

21.55 Iodine-131 is a convenient radioisotope to monitor thyroid activity in humans. It is a beta emitter with a half-life of 8.02 days. The thyroid is the only gland in the body that uses iodine. A person undergoing a test of thyroid activity drinks a solution of NaI, in which only a small fraction of the iodide is radioactive. (**a**) Which of the following best explains why NaI is a good choice for the source of iodine: (i) The half-life of iodine-131 is longer in an iodide ion than it is in an iodine atom. (ii) NaI is soluble in water and will therefore be readily absorbed into bodily fluids. (iii) The sodium ion absorbs most of the radiation emitted by the radioactive iodine. (**b**) A normal thyroid will take up about 12% of the ingested iodide in a few hours. How long will it take for the radioactive iodide taken up and held by the thyroid to decay to 0.01% of the original amount?

21.56 Why is it important that radioisotopes used as diagnostic tools in nuclear medicine produce gamma radiation when they decay? Why are alpha emitters not used as diagnostic tools?

21.57 (**a**) Which of the following are required characteristics of an isotope to be used as a fuel in a nuclear power reactor? (i) It must emit gamma radiation. (ii) On decay, it must release two or more neutrons. (iii) It must have a half-life less than one hour. (iv) It must undergo fission upon the absorption of a neutron. (**b**) What is the most common fissionable isotope in a commercial nuclear power reactor?

21.58 Which of the following statements about the uranium used in nuclear reactors is or are *true*? (i) Natural uranium has too little ${}^{235}\text{U}$ to be used as a fuel. (ii) ${}^{238}\text{U}$ cannot be used as a fuel because it forms a supercritical mass too easily. (iii) To be used as fuel, uranium must be enriched so that it is more than 50% ${}^{235}\text{U}$ in composition. (iv) The neutron-induced fission of ${}^{235}\text{U}$ releases more neutrons per nucleus than fission of ${}^{238}\text{U}$.

21.59 What is the function of the control rods in a nuclear reactor? What substances are used to construct control rods? Why are these substances chosen?

21.60 (**a**) What is the function of the moderator in a nuclear reactor? (**b**) What substance acts as the moderator in a pressurized water generator? (**c**) What other substances are used as a moderator in nuclear reactor designs?

21.61 Complete and balance the nuclear equations for the following fission or fusion reactions:

(**a**) ${}^{2}_{1}\text{H} + {}^{2}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + \_$

(**b**) ${}^{239}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{133}_{51}\text{Sb} + {}^{98}_{41}\text{Nb} + \_\;{}^{1}_{0}\text{n}$

21.62 Complete and balance the nuclear equations for the following fission reactions:

(**a**) ${}^{235}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{160}_{62}\text{Sm} + {}^{72}_{30}\text{Zn} + \_\;{}^{1}_{0}\text{n}$

(**b**) ${}^{239}_{94}\text{Pu} + {}^{1}_{0}\text{n} \longrightarrow {}^{144}_{58}\text{Ce} + \_ + 2\,{}^{1}_{0}\text{n}$

21.63 A portion of the Sun's energy comes from the following reaction:

$$ 4\,{}^{1}_{1}\text{H} \longrightarrow {}^{4}_{2}\text{He} + 2\,{}^{0}_{1}\text{e} $$

Use the mass of the helium-4 nucleus given in Table 21.7 to determine how much energy is released per mole of hydrogen atoms.

21.64 The spent fuel elements from a fission reactor are much more intensely radioactive than the original fuel elements. (**a**) What does this tell you about the products of the fission process in relationship to the belt of stability (see Figure 21.2)? (**b**) Given that only two or three neutrons are released per fission event and knowing that the nucleus undergoing fission has a neutron-to-proton ratio characteristic of a heavy nucleus, what sorts of decay would you expect to be dominant among the fission products?

21.65 Which type or types of nuclear reactors have the following characteristics?

(**a**) Does not use a secondary coolant

(**b**) Creates more fissionable material than it consumes

(**c**) Uses a gas, such as He or CO_2, as the primary coolant

21.66 Which type or types of nuclear reactors have the following characteristics?

(**a**) Can use natural uranium as a fuel

(**b**) Does not use a moderator

(**c**) Can be refueled without shutting down

21.67 Hydroxyl radicals can pluck hydrogen atoms from molecules ("hydrogen abstraction"), and hydroxide ions can pluck protons from molecules ("deprotonation"). Write the reaction equations and Lewis dot structures for the hydrogen abstraction and deprotonation reactions for the generic carboxylic acid R—COOH with hydroxyl radical and hydroxide ion, respectively. Why is hydroxyl radical more toxic to living systems than hydroxide ion?

21.68 Which are classified as ionizing radiation: X rays, alpha particles, microwaves from a cell phone, and gamma rays?

21.69 A laboratory rat is exposed to an alpha-radiation source whose activity is 14.3 mCi. (**a**) What is the activity of the radiation in disintegrations per second? In becquerels? (**b**) The rat has a mass of 385 g and is exposed to the radiation for 14.0 s, absorbing 35% of the emitted alpha particles, each having an energy of 9.12×10^{-13} J. Calculate the absorbed dose in millirads and grays. (**c**) If the RBE of the radiation is 9.5, calculate the effective absorbed dose in mrem and Sv.

21.70 A 65-kg person is accidentally exposed for 240 s to a 15-mCi source of beta radiation coming from a sample of ${}^{90}\text{Sr}$. (**a**) What is the activity of the radiation source in disintegrations per second? In becquerels? (**b**) Each beta particle has an energy of 8.75×10^{-14} J, and 7.5% of the radiation is absorbed by the person. Assuming that the absorbed radiation is spread over the person's entire body, calculate the absorbed dose in rads and in grays. (**c**) If the RBE of the beta particles is 1.0, what is the effective dose in mrem and in sieverts? (**d**) Is the radiation dose equal to, greater than, or less than that for a typical mammogram (300 mrem)?

Additional Exercises

21.71 The table provided gives the number of protons (p) and neutrons (n) for four isotopes, identified only as (i)–(iv). (**a**) Write the symbol for each of the isotopes. (**b**) Which of the isotopes is most likely to be unstable? (**c**) Which of the isotopes involves a magic number of protons and/or neutrons? (**d**) Which isotope will yield potassium-39 following positron emission?

	(i)	(ii)	(iii)	(iv)
p	19	19	20	20
n	19	21	19	20

21.72 Radon-222 decays to a stable nucleus by a series of three alpha emissions and two beta emissions. What is the stable nucleus that is formed?

21.73 Equation 21.28 is the nuclear reaction responsible for much of the helium-4 production in the Sun. How much energy is released in this reaction?

21.74 Chlorine has two stable nuclides, ${}^{35}\text{Cl}$ and ${}^{37}\text{Cl}$. In contrast, ${}^{36}\text{Cl}$ is a radioactive nuclide that decays by beta emission. (**a**) What is the product of decay of ${}^{36}\text{Cl}$? (**b**) Which of the following is the most likely explanation as to why ${}^{36}\text{Cl}$ is less stable than either ${}^{35}\text{Cl}$ or ${}^{37}\text{Cl}$: (i) The neutron-to-proton ratio for ${}^{36}\text{Cl}$ is higher than that for the other two isotopes. (ii) Nuclides with odd mass numbers are more stable than those with even mass numbers. (iii) ${}^{36}\text{Cl}$ has an odd number of protons and an odd number of neutrons.

21.75 When two protons fuse in a star, the product is ${}^{2}\text{H}$ plus a positron. Write the nuclear equation for this process.

21.76 Nuclear scientists have synthesized approximately 1600 nuclei not known in nature. More might be discovered with heavy-ion bombardment using high-energy particle accelerators. Complete and balance the following reactions, which involve heavy-ion bombardments:

(**a**) ${}^{6}_{3}\text{Li} + {}^{56}_{28}\text{Ni} \longrightarrow ?$

(**b**) ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \longrightarrow {}^{147}_{62}\text{Sm} + ?$

(**c**) ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \longrightarrow {}^{116}_{46}\text{Pd} + ?$

(**d**) ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \longrightarrow {}^{70}_{30}\text{Zn} + 4\,{}^{1}_{0}\text{n} + 2\,?$

21.77 In 2010, a team of scientists from Russia and the United States reported the creation of the first atom of element 117, which is named tennessine and whose symbol is Ts. The synthesis involved the collision of a target of ${}^{249}_{97}\text{Bk}$ with accelerated ions of an isotope which we will denote Q. The product atom, which we will call Z, immediately releases neutrons and forms ${}^{294}_{117}\text{Ts}$:

$$ {}^{249}_{97}\text{Bk} + \text{Q} \longrightarrow \text{Z} \longrightarrow {}^{294}_{117}\text{Ts} + 3\,{}^{1}_{0}\text{n} $$

(**a**) What are the identities of isotopes Q and Z? (**b**) Isotope Q is unusual in that it is very long-lived (its half-life is on the order of 10^{19} yr) in spite of having an unfavorable neutron-to-proton ratio (Figure 21.1). Can you propose a reason for its unusual stability? (**c**) Collision of ions of isotope Q with a target was also used to produce the first atoms of livermorium, Lv. The initial product of this collision was ${}^{296}_{116}\text{Lv}$. What was the target isotope with which Q collided in this experiment?

21.78 The synthetic radioisotope technetium-99, which decays by beta emission, is the most widely used isotope in nuclear medicine. The following data were collected on a sample of ${}^{99}\text{Tc}$:

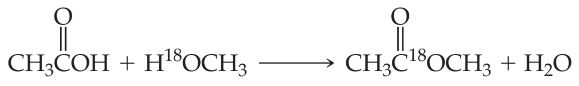
Disintegrations per Minute	Time (h)
180	0
130	2.5
104	5.0
77	7.5
59	10.0
46	12.5
24	17.5

Using these data, make an appropriate graph and curve fit to determine the half-life.

21.79 According to current regulations, the maximum permissible dose of strontium-90 in the body of an adult is 1 μCi (1×10^{-6} Ci).

Using the relationship rate = kN, calculate the number of atoms of strontium-90 to which this dose corresponds. To what mass of strontium-90 does this correspond? The half-life for strontium-90 is 28.8 yr.

21.80 Methyl acetate (CH_3COOCH_3) is formed by the reaction of acetic acid with methyl alcohol. If the methyl alcohol is labeled with oxygen-18, the oxygen-18 ends up in the methyl acetate:



$$CH_3\overset{\overset{O}{\|}}{C}OH + H^{18}OCH_3 \longrightarrow CH_3\overset{\overset{O}{\|}}{C}{}^{18}OCH_3 + H_2O$$

(**a**) Do the C—OH bond of the acid and the O—H bond of the alcohol break in the reaction, or do the O—H bond of the acid and the C—OH bond of the alcohol break? (**b**) Imagine a similar experiment using the radioisotope ${}^3H$, which is called *tritium* and is usually denoted T. Would the reaction between CH_3COOH and $TOCH_3$ provide the same information about which bond is broken as does the above experiment with $H^{18}OCH_3$?

21.81 Each of the following transmutations produces a radionuclide used in positron emission tomography (PET). (**a**) In equations (i) and (ii), identify the species signified as "X." (**b**) In equation (iii), one of the species is indicated as "d." What do you think it represents?

(**i**) ${}^{14}N(p, \alpha)X$
(**ii**) ${}^{18}O(p, X){}^{18}F$
(**iii**) ${}^{14}N(d, n){}^{15}O$

21.82 The nuclear masses of ${}^7Be$, ${}^9Be$, and ${}^{10}Be$ are 7.0147, 9.0100, and 10.0113 amu, respectively. Which of these nuclei has the largest binding energy per nucleon?

21.83 A 26.00-g sample of water containing tritium, ${}^3_1H$, emits 1.50×10^3 beta particles per second. Tritium is a weak beta emitter with a half-life of 12.3 yr. What fraction of all the hydrogen in the water sample is tritium?

21.84 The Sun radiates energy into space at the rate of 3.9×10^{26} J/s. (**a**) Calculate the rate of mass loss from the Sun in kg/s. (**b**) It is estimated that the Sun contains 9×10^{56} free protons. How many protons per second are consumed in nuclear reactions in the Sun?

21.85 The average energy released in the fission of a single uranium-235 nucleus is about 3×10^{-11} J. If the conversion of this energy to electricity in a nuclear power plant is 40% efficient, what mass of uranium-235 undergoes fission in a year in a plant that produces 1000 megawatts? Recall that a watt is 1 J/s.

21.86 Tests on human subjects in Boston in 1965 and 1966, following the era of atomic bomb testing, revealed average quantities of about 2 pCi of plutonium radioactivity in the average person. How many disintegrations per second does this level of activity imply? If each alpha particle deposits 8×10^{-13} J of energy and if the average person weighs 75 kg, calculate the number of rads and rems of radiation in 1 yr from such a level of plutonium.

21.87 A 53.8-mg sample of sodium perchlorate contains radioactive chlorine-36 (whose atomic mass is 36.0 amu). If 29.6% of the chlorine atoms in the sample are chlorine-36 and the remainder are naturally occurring nonradioactive chlorine atoms, how many disintegrations per second are produced by this sample? The half-life of chlorine-36 is 3.0×10^5 yr.

21.88 Naturally found uranium consists of 99.274% ${}^{238}U$, 0.720% ${}^{235}U$, and 0.006% ${}^{233}U$. As we have seen, ${}^{235}U$ is the isotope that can undergo a nuclear chain reaction. Most of the ${}^{235}U$ used in the first atomic bomb was obtained by gaseous diffusion of uranium hexafluoride, $UF_6(g)$. (**a**) What is the mass of UF_6 in a 30.0-L vessel of UF_6 at a pressure of 695 torr at 350 K? (**b**) What is the mass of ${}^{235}U$ in the sample described in part (a)? (**c**) Now suppose that the UF_6 is diffused through a porous barrier and that the change in the ratio of ${}^{238}U$ and ${}^{235}U$ in the diffused gas can be described by Equation 10.24. What is the mass of ${}^{235}U$ in a sample of the diffused gas analogous to that in part (a)? (**d**) After one more cycle of gaseous diffusion, what is the percentage of ${}^{235}UF_6$ in the sample?

21.89 A sample of an alpha emitter having an activity of 0.18 Ci is stored in a 25.0-mL sealed container at 22 °C for 245 days. (**a**) How many alpha particles are formed during this time? (**b**) Assuming that each alpha particle is converted to a helium atom, what is the partial pressure of helium gas in the container after this 245-day period?

21.90 Charcoal samples from Stonehenge in England were burned in O_2, and the resultant CO_2 gas bubbled into a solution of $Ca(OH)_2$ (limewater), resulting in the precipitation of $CaCO_3$. The $CaCO_3$ was removed by filtration and dried. A 788-mg sample of the $CaCO_3$ had a radioactivity of 1.5×10^{-2} Bq due to carbon-14. By comparison, living organisms undergo 15.3 disintegrations per minute per gram of carbon. Using the half-life of carbon-14, 5730 yr, calculate the age of the charcoal sample.

Design an Experiment

Because radioactivity can have harmful effects on human health, stringent experimental procedures and precautions are required when undertaking experiments on radioactive materials. As such, we typically do not have experiments involving radioactive substances in general chemistry laboratories. We can nevertheless ponder the design of some hypothetical experiments that would allow us to explore some of the properties of radium, which was discovered by Marie and Pierre Curie in 1898.

(**a**) A key aspect of the discovery of radium was Marie Curie's observation that *pitchblende*, a natural ore of uranium, had greater radioactivity than pure uranium metal. Design an experiment to reproduce this observation and to obtain a ratio of the activity of pitchblende relative to that of pure uranium.

(**b**) Radium was first isolated as halide salts. Suppose you had pure samples of radium metal and radium bromide. The sample sizes are on the order of milligrams and are not amenable to the usual forms of elemental analysis. Could you use a device that measures radioactivity quantitatively to determine the empirical formula of radium bromide? What information must you use that the Curies may not have had at the time of their discovery?

(**c**) Suppose you had a 1-yr time period in order to measure the half-life of radium and related elements. You have some pure samples and a device that measures radioactivity quantitatively. Could you determine the half-life of the elements in the samples? Would you have different experimental constraints depending on whether the half-life were 10 yr or 1000 yr?

(**d**) Before its negative health effects were better understood, small amounts of radium salts were used in “glow in the dark” watches, such as the one shown here. The glow is not due to the radioactivity of radium directly; rather, the radium is combined with a luminescent substance, such as zinc sulfide, which glows when it is exposed to radiation. Suppose you had pure samples of radium and zinc sulfide. How could you determine whether the glow of zinc sulfide is due to alpha, beta, or gamma radiation? What type of device could you design to use the glow as a quantitative measure of the amount of radioactivity in a sample?

22

CHEMISTRY OF THE NONMETALS

▲ **A TROPICAL BEACH.** The water, sand, and air are composed of nonmetals.

Much of the world is composed of nonmetals. Water, for example, is H_2O, and sand is mostly SiO_2. Although we cannot see it, the air contains principally N_2 and O_2 with much lesser amounts of other nonmetallic substances.

In this chapter, we take a panoramic view of the descriptive chemistry of the nonmetallic elements, starting with hydrogen and progressing group by group across the periodic table. We consider how the elements occur in nature, how they are isolated from their sources, and how they are used. We emphasize hydrogen, oxygen, nitrogen, and carbon because these four nonmetals form many commercially important compounds and account for 99% of the atoms required by living cells.

As you study this *descriptive chemistry*, it is important to look for trends rather than trying to memorize all the facts presented. The periodic table is your most valuable tool in this task.

WHAT'S AHEAD

22.1 ▶ Periodic Trends and Chemical Reactions Review periodic trends and types of chemical reactions in order to identify general patterns of behavior.

22.2 ▶ Hydrogen Explore hydrogen, which forms compounds with most other nonmetals and with many metals.

22.3 ▶ Group 8A: The Noble Gases Examine the noble gases, the elements of group 8A, which exhibit very limited chemical reactivity.

22.4 ▶ Group 7A: The Halogens Explore the most electronegative elements: the halogens, group 7A.

22.5 ▶ Oxygen Learn about oxygen, the most abundant element by mass in both Earth's crust and the human body, and the oxide and peroxide compounds it forms.

22.6 ▶ The Other Group 6A Elements: S, Se, Te, and Po Study the other members of group 6A (S, Se, Te, and Po), of which sulfur is the most important.

22.7 ▶ Nitrogen Explore nitrogen, a key component of our atmosphere. It forms compounds in which its oxidation number ranges from −3 to +5.

22.8 ▶ The Other Group 5A Elements: P, As, Sb, and Bi Examine the other members of group 5A, taking a closer look at phosphorus—the most commercially important one and the only one that plays an important and beneficial role in biological systems.

22.9 ▶ Carbon Learn about the inorganic compounds of carbon.

22.10 ▶ The Other Group 4A Elements: Si, Ge, Sn, and Pb Explore silicon, the element most abundant and significant of the heavier members of group 4A.

22.11 ▶ Boron Examine boron—the sole nonmetallic element of group 3A.

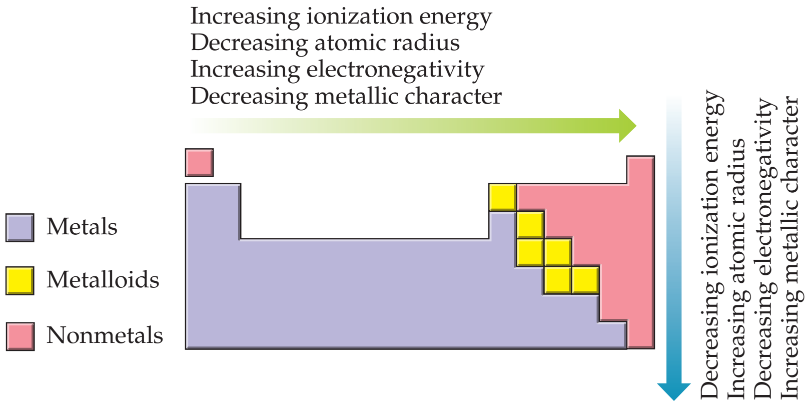
22.1 | Periodic Trends and Chemical Reactions

Learning Objectives

When you finish Section 22.1, you should be able to

- Predict trends in the properties of the elements based on their position in the periodic table.
- Predict which elements in a group are most likely to undergo π bonding.
- Predict the products of chemical reactions based on combustion or acid–base chemistry.

Recall that we can classify elements as metals, metalloids, and nonmetals. (Section 7.5) Except for hydrogen, which is a special case, the nonmetals occupy the upper right portion of the periodic table. This division of elements relates nicely to trends in their properties as summarized in **Figure 22.1**. Electronegativity, for example, increases as we move left to right across a period and decreases as we move down a group. The nonmetals thus have higher electronegativities than the metals. This difference leads to the formation of ionic solids in reactions between metals and nonmetals. (Sections 7.5, 8.2, and 8.4) In contrast, compounds formed between two or more nonmetals are usually molecular substances. (Sections 7.7 and 8.4)

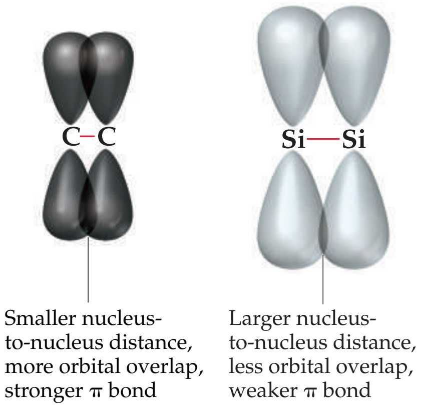


Increasing ionization energy
Decreasing atomic radius
Increasing electronegativity
Decreasing metallic character
Metals
Metalloids
Nonmetals
Decreasing ionization energy
Increasing atomic radius
Decreasing electronegativity
Increasing metallic character

▲ **Figure 22.1** **Trends in elemental properties.**

The chemistry exhibited by the first member of a nonmetal group can differ from that of subsequent members in important ways. Two differences are particularly notable:

- The first member follows the octet rule, but heavier group members can expand their octet. (Section 8.7) For example, nitrogen is able to bond to a maximum of three Cl atoms, NCl_3, whereas phosphorus can bond to five, PCl_5. The small size of nitrogen is largely responsible for this difference.
- The first member can more readily form π bonds and hence double and triple bonds. This trend is also due, in part, to size because small atoms are able to approach each other more closely. As a result, the overlap of *p* orbitals, which results in the formation of π bonds, is more effective for the first element in each group (**Figure 22.2**). More effective overlap means stronger π bonds, reflected in bond enthalpies. (Sections 5.8 and 8.8) For example, the difference between the enthalpies of the C—C bond and the C═C bond is about 270 kJ/mol (Table 8.3); this large value reflects the "strength" of a carbon–carbon π bond. On the other hand, the difference between Si—Si and Si═Si bonds is only about 100 kJ/mol, significantly lower than that for carbon, reflecting much weaker π bonding.



C—C
Si—Si
Smaller nucleus-to-nucleus distance, more orbital overlap, stronger π bond
Larger nucleus-to-nucleus distance, less orbital overlap, weaker π bond

▲ **Figure 22.2** **Comparing π bonds in period 2 and period 3 elements.**

As we shall see, π bonds are particularly important in the chemistry of carbon, nitrogen, and oxygen, each the first member in its group. The heavier elements in these groups have a tendency to form only single bonds.

Sample Exercise 22.1

Identifying Elemental Properties

Of the elements Li, K, N, P, and Ne, (**a**) which is the most electronegative, (**b**) which has the greatest metallic character, (**c**) which can bond to more than four atoms in a molecule, and (**d**) which forms π bonds most readily?

SOLUTION

Analyze We are given a list of elements and asked to predict several properties that can be related to periodic trends.

Plan We can use Figures 22.1 and 22.2 to guide us to the answers.

Solve

(**a**) Electronegativity increases as we proceed toward the upper right portion of the periodic table, excluding the noble gases. Thus, N is the most electronegative element of our choices.

(**b**) Metallic character correlates inversely with electronegativity—the less electronegative an element, the greater its metallic character. The element with the greatest metallic character is therefore K, which is closest to the lower left corner of the periodic table.

(**c**) Nonmetals tend to form molecular compounds, so we can narrow our choice to the three nonmetals on the list: N, P, and Ne. To form more than four bonds, an element must be able to expand its valence shell to allow more than an octet of electrons around it. Valence-shell expansion occurs for period 3 elements and below; N and Ne are both in period 2 and do not undergo valence-shell expansion. Thus, the answer is P.

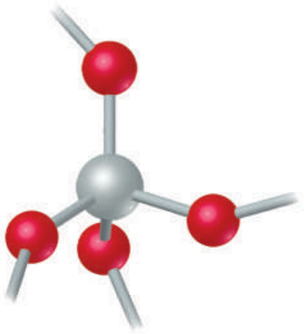
(**d**) Period 2 nonmetals form π bonds more readily than elements in period 3 and below. There are no compounds known that contain covalent bonds to Ne. Thus, N is the element from the list that forms π bonds most readily.

▶ Practice Exercise

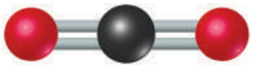
Of the elements Be, C, Cl, Sb, and Cs, (**a**) which has the lowest electronegativity, (**b**) which has the greatest nonmetallic character, (**c**) which is most likely to participate in extensive π bonding, and (**d**) which is most likely to be a metalloid?

The ready ability of period 2 elements to form π bonds is an important factor in determining the elemental forms of these elements. Compare, for example, carbon and silicon. Carbon has five major crystalline *allotropes*: diamond, graphite, buckminsterfullerene, graphene, and carbon nanotubes. (Sections 12.5 and 12.7) Diamond is a covalent-network solid that has C—C σ bonds but no π bonds. Other allotropes of carbon have π bonds that result from the sideways overlap of *p* orbitals. Elemental silicon, however, exists only as a diamond-like covalent-network solid with σ bonds; it has no forms analogous to graphite, buckminsterfullerene, graphene, or carbon nanotubes, probably because Si—Si π bonds are too weak.

We likewise see significant differences in the dioxides of carbon and silicon as a result of their relative abilities to form π bonds (**Figure 22.3**). CO_2 is a molecular substance containing C═O double bonds, whereas SiO_2 is a covalent-network solid in which four oxygen atoms are bonded to each silicon atom by single bonds, forming an extended structure that has the empirical formula SiO_2.



Fragment of extended SiO_2 lattice; Si forms only single bonds



CO_2; C forms double bonds

▲ **Figure 22.3 Comparison of the bonds in SiO_2 and CO_2.**

Chemical Reactions

Because O_2 and H_2O are abundant in our environment, it is particularly important to consider how these substances react with other compounds. About one-third of the reactions discussed in this chapter involve either O_2 (oxidation or combustion reactions) or H_2O (especially proton-transfer reactions).

In combustion reactions (Section 3.2), hydrogen-containing compounds produce H_2O. Carbon-containing ones produce CO_2 (unless the amount of O_2 is insufficient, in which case CO or even C can form). Nitrogen-containing compounds tend to form N_2, although NO can form in special cases or in small amounts. The following reaction illustrates these points:

$$4\,CH_3NH_2(g) + 9\,O_2(g) \longrightarrow 4\,CO_2(g) + 10\,H_2O(g) + 2\,N_2(g) \qquad [22.1]$$

The formation of H_2O, CO_2, and N_2 reflects the high thermodynamic stability of these substances, indicated by the large bond energies for the O—H, C═O, and N≡N bonds (463, 799, and 941 kJ/mol, respectively). (Sections 5.8 and 8.8)

When dealing with proton-transfer reactions, remember that the weaker a Brønsted–Lowry acid, the stronger its conjugate base. (Section 16.2) For example, H_2, OH^-, NH_3, and CH_4 are exceedingly weak proton donors that have *no* tendency to act as acids in water. Thus, the species formed by removing one or more protons from them are extremely strong bases. All of them react readily with water, removing protons from H_2O to form OH^-. Two representative reactions are:

$$CH_3^-(aq) + H_2O(l) \longrightarrow CH_4(g) + OH^-(aq) \qquad [22.2]$$

$$N^{3-}(aq) + 3\,H_2O(l) \longrightarrow NH_3(aq) + 3\,OH^-(aq) \qquad [22.3]$$

Sample Exercise 22.2

Predicting the Products of Chemical Reactions

Predict the products formed in each of the following reactions, and write a balanced equation:

(**a**) $CH_3NHNH_2(g) + O_2(g) \longrightarrow ?$ (**b**) $Mg_3P_2(s) + H_2O(l) \longrightarrow ?$

SOLUTION

Analyze We are given the reactants for two chemical equations, and we are asked to predict the products and then balance the equations.

Plan We need to examine the reactants to see if we might recognize a reaction type. In (**a**) the carbon compound is reacting with O_2, which suggests a combustion reaction. In (**b**) water reacts with an ionic compound. The anion P^{3-} is a strong base and H_2O is able to act as an acid, so the reactants suggest an acid–base (proton-transfer) reaction.

Solve

(**a**) Based on the elemental composition of the carbon compound, this combustion reaction should produce CO_2, H_2O, and N_2:

$$2\,CH_3NHNH_2(g) + 5\,O_2(g) \longrightarrow 2\,CO_2(g) + 6\,H_2O(g) + 2\,N_2(g)$$

(**b**) Mg_3P_2 is ionic, consisting of Mg^{2+} and P^{3-} ions. The P^{3-} ion, like N^{3-}, has a strong affinity for protons and reacts with H_2O to form OH^- and PH_3 (PH^{2-}, PH_2^-, and PH_3 are all exceedingly weak proton donors).

$$Mg_3P_2(s) + 6\,H_2O(l) \longrightarrow 2\,PH_3(g) + 3\,Mg(OH)_2(s)$$

$Mg(OH)_2$ has low solubility in water and will precipitate.

Practice Exercise

Write a balanced equation for the reaction of solid sodium hydride with water.

Self-Assessment Exercises

SAE 22.1 Which of the elements Na, Rb, F, Si, and Ne is the most electronegative? (**a**) F (**b**) Na (**c**) Rb (**d**) Si

SAE 22.2 Which of the elements Na, Rb, F, Si, and Ne has the greatest metallic character? (**a**) Na (**b**) F (**c**) Si (**d**) Rb (**e**) Ne

SAE 22.3 Which of the elements Rb, F, Si, and Ne most readily forms a positive ion? (**a**) F (**b**) Si (**c**) Rb (**d**) Ne

SAE 22.4 Which of the elements Al, N, P, and As is most likely to form multiple π bonds with itself? (**a**) Al (**b**) N (**c**) P (**d**) As

SAE 22.5 Complete and balance the following equation:

$$C_2H_5OH(l) + O_2(g) \longrightarrow$$

(**a**) $C_2H_5OH(l) + 2\,O_2(g) \longrightarrow 2\,H_2O(l) + 2\,CHO_2(g)$
(**b**) $C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 3\,H_2O(l) + 2\,CO_2(g)$
(**c**) $3\,C_2H_5OH(l) + O_2(g) \longrightarrow H_2O(l) + 6\,CO_2(g)$
(**d**) $C_2H_5OH(l) + 3\,H_2O(l) \longrightarrow 6\,H_2(g) + 2\,CO_2(g)$

22.2 | Hydrogen

Learning Objectives

When you finish Section 22.2, you should be able to:

- Compare and contrast the isotopes of hydrogen.
- Classify a given hydride as ionic, metallic, or molecular.
- Distinguish the properties and reactivity of hydrogen compared to other elements.

Because hydrogen produces water when burned in air, the French chemist Antoine Lavoisier (1734–1794) gave it the name *hydrogen*, which means "water producer" (Greek: *hydro*, water; *gennao*, to produce).

Hydrogen is the most abundant element in the universe. [See the "Chemistry and Sustainability" box on "Hydrogen and Helium." (Section 10.6)] It is the nuclear fuel consumed by our Sun and other stars to produce energy. (Section 21.8) Although about 75% of the known mass of the universe is hydrogen, it constitutes only 0.87% of Earth's mass. Most of the hydrogen on our planet is found associated with oxygen. Water, which is 11% hydrogen by mass, is the most abundant hydrogen compound.

Isotopes of Hydrogen

The most common isotope of hydrogen, ${}^{1}_{1}H$, has a nucleus consisting of a single proton. This isotope, sometimes referred to as **protium**,* makes up 99.9844% of naturally occurring hydrogen.

Two other isotopes are known: ${}^{2}_{1}H$, whose nucleus contains a proton and a neutron, and ${}^{3}_{1}H$, whose nucleus contains a proton and two neutrons. The ${}^{2}_{1}H$ isotope, **deuterium**, makes up 0.0156% of naturally occurring hydrogen. It is not radioactive, and it is often given the symbol D in chemical formulas, as in D_2O (deuterium oxide), which is known as *heavy water*.

Because an atom of deuterium is about twice as massive as an atom of protium, the properties of deuterium-containing substances vary somewhat from those of the protium-containing analogs. For example, the normal melting and boiling points of D_2O are 3.81 °C and 101.42 °C, respectively, versus 0.00 °C and 100.00 °C for H_2O. Not surprisingly, the density of D_2O at 25 °C (1.104 g/mL) is greater than that of H_2O (0.997 g/mL). Replacing protium with deuterium (a process called *deuteration*) can also have a profound effect on reaction rates, a phenomenon called a *kinetic-isotope effect*. For example, heavy water can be obtained from the electrolysis $[2\,H_2O(l) \longrightarrow 2\,H_2(g) + O_2(g)]$ of ordinary water because the small amount of naturally occurring D_2O in the sample undergoes electrolysis more slowly than H_2O and, therefore, becomes concentrated during the reaction.

The third isotope, ${}^{3}_{1}H$, **tritium**, is radioactive, with a half-life of 12.3 yr:

$$ {}^{3}_{1}H \longrightarrow {}^{3}_{2}He + {}^{\ 0}_{-1}e \quad t_{1/2} = 12.3\text{ yr} \qquad [22.4] $$

Because of its short half-life, only trace quantities of tritium exist naturally. The isotope can be synthesized in nuclear reactors by neutron bombardment of lithium-6:

$$ {}^{6}_{3}Li + {}^{1}_{0}n \longrightarrow {}^{3}_{1}H + {}^{4}_{2}He \qquad [22.5] $$

Deuterium and tritium are useful in studying reactions of compounds containing hydrogen. A compound is "labeled" by replacing one or more ordinary hydrogen atoms with deuterium or tritium at specific locations in a molecule. By comparing the locations of the label atoms in reactants and products, the reaction mechanism can often be inferred. When methyl alcohol (CH_3OH) is placed in D_2O, for example, the H atom of the O—H bond exchanges rapidly with the D atoms, forming CH_3OD. The H atoms of the CH_3 group do not exchange. This experiment demonstrates the kinetic stability of C—H bonds and reveals the speed at which the O—H bond in the molecule breaks and re-forms.

Properties of Hydrogen

Hydrogen is the only element that is not a member of any family in the periodic table. Because of its $1s^1$ electron configuration, it is generally placed above lithium in the table. However, it is definitely *not* an alkali metal. It forms a positive ion much less readily than any alkali metal. The ionization energy of the hydrogen atom is 1312 kJ/mol, whereas that of lithium is 520 kJ/mol.

Hydrogen is sometimes placed above the halogens in the periodic table because the hydrogen atom can pick up one electron to form the *hydride ion*, H^-, which has the same electron configuration as helium. However, the electron affinity of hydrogen, $EA = -73$ kJ/mol, is not as large as that of any halogen. In general, hydrogen shows no closer resemblance to the halogens than it does to the alkali metals.

Elemental hydrogen exists at room temperature as a colorless, odorless, tasteless gas composed of diatomic molecules. We can call H_2 *dihydrogen*, but it is more commonly referred to as either *molecular hydrogen* or simply hydrogen. Because H_2 is nonpolar and has only two electrons, attractive forces between molecules are extremely weak. As a result, its melting point (−259 °C) and boiling point (−253 °C) are very low.

The H—H bond enthalpy (436 kJ/mol) is high for a single bond. (Table 8.3) By comparison, the Cl—Cl bond enthalpy is only 242 kJ/mol. Because H_2 has a strong bond, most reactions involving H_2 are slow at room temperature. However, the molecule is readily activated by heat, irradiation, or catalysis. The activation generally produces hydrogen atoms, which are very reactive. Once H_2 is activated, it reacts rapidly and exothermically with a wide variety of substances.

---

*Giving unique names to isotopes is limited to hydrogen. Because of the proportionally large differences in their masses, the isotopes of H show appreciably more differences in their properties than isotopes of heavier elements.

Hydrogen forms strong covalent bonds with many other elements, including oxygen; the O—H bond enthalpy is 463 kJ/mol. The formation of the strong O—H bond makes hydrogen an effective reducing agent for many metal oxides. When H_2 is passed over heated CuO, for example, copper is produced:

$$\mathrm{CuO}(s) + \mathrm{H_2}(g) \longrightarrow \mathrm{Cu}(s) + \mathrm{H_2O}(g) \qquad [22.6]$$

When H_2 is ignited in air, a vigorous reaction occurs, forming H_2O. Air containing as little as 4% H_2 by volume is potentially explosive. Combustion of hydrogen–oxygen mixtures is used in liquid-fuel rocket engines to launch space vehicles. The hydrogen and oxygen are stored at low temperatures in liquid form.

Production of Hydrogen

When a small quantity of H_2 is needed in the laboratory, it is usually obtained by the reaction between an active metal such as zinc and a dilute strong acid such as HCl or H_2SO_4:

$$\mathrm{Zn}(s) + 2\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Zn^{2+}}(aq) + \mathrm{H_2}(g) \qquad [22.7]$$

Large quantities of H_2 are produced by reacting methane, principally from natural gas, with steam at 1100 °C. We can view this process as involving two reactions:

$$\mathrm{CH_4}(g) + \mathrm{H_2O}(g) \longrightarrow \mathrm{CO}(g) + 3\,\mathrm{H_2}(g) \qquad [22.8]$$

$$\mathrm{CO}(g) + \mathrm{H_2O}(g) \longrightarrow \mathrm{CO_2}(g) + \mathrm{H_2}(g) \qquad [22.9]$$

Equation 22.8 is known as *steam reforming* and is an endothermic reaction. Equation 22.9 shows that one product of steam reforming, CO, can react with water to produce CO_2 and H_2. Equation 22.9 is known as the *water-gas shift reaction* and is slightly exothermic. Taken together, the products of Equations 22.8 and 22.9 (CO, CO_2, and H_2) are referred to as *syngas*. Syngas is used as industrial fuel in electricity generation. Both Equations 22.8 and 22.9 require catalysts to proceed.

Carbon heated with water to about 1000 °C is another source of H_2:

$$\mathrm{C}(s) + \mathrm{H_2O}(g) \longrightarrow \mathrm{H_2}(g) + \mathrm{CO}(g) \qquad [22.10]$$

This mixture, known as *water gas*, is also used as an industrial fuel. Water gas is a product of Equation 22.8 as well.

Electrolysis of water consumes too much energy and is consequently too costly to be used commercially to produce H_2. However, H_2 is produced as a by-product in the electrolysis of brine (NaCl) solutions in the course of commercial Cl_2 and NaOH manufacture:

$$2\,\mathrm{NaCl}(aq) + 2\,\mathrm{H_2O}(l) \xrightarrow{\text{electrolysis}} \mathrm{H_2}(g) + \mathrm{Cl_2}(g) + 2\,\mathrm{NaOH}(aq) \qquad [22.11]$$

CHEMISTRY AND SUSTAINABILITY The Hydrogen Economy

The reaction of hydrogen with oxygen is highly exothermic:

$$2\,\mathrm{H_2}(g) + \mathrm{O_2}(g) \longrightarrow 2\,\mathrm{H_2O}(g) \quad \Delta H = -483.6\ \mathrm{kJ} \qquad [22.12]$$

Because H_2 has a low molar mass and a high enthalpy of combustion, it has a high-energy density by mass. (That is, its combustion produces high energy per gram.) The only product of the reaction is water vapor, which means that hydrogen is environmentally cleaner than fossil fuels. Thus, the prospect of using hydrogen widely as a fuel is attractive. Furthermore, the hydrogen can be utilized as a fuel in hydrogen fuel cells, enhancing the efficiency of its use. (Section 20.7)

The term *hydrogen economy* is used to describe the concept of delivering and using hydrogen as a fuel in place of fossil fuels. [This concept was also mentioned in the "Chemistry and Sustainability" box on "Hydrogen and Helium." (Section 10.6)] In order to develop a hydrogen economy, it would be necessary to generate elemental hydrogen on a large scale and arrange for its transport and storage. These matters provide significant technical challenges.

Figure 22.4 illustrates various sources and uses of H_2 fuel. The generation of H_2 through electrolysis of water is in principle the cleanest route, because this process—the reverse of Equation 22.12—produces only hydrogen and oxygen. (Figure 1.6 and Section 20.9) However, the energy required to electrolyze water must come from somewhere. If we burn fossil fuels to generate this energy, we have not advanced very far toward a true hydrogen economy. If the energy for electrolysis came instead from a hydroelectric or nuclear power plant, solar cells, or wind generators, consumption of nonrenewable energy sources and undesired production of CO_2 could be avoided.

The storage of hydrogen is another technical obstacle that must be overcome in developing a hydrogen economy. Although $H_2(g)$ has a high-energy density by mass, it has a low-energy density by volume. Thus, storing hydrogen as a gas requires a large volume compared to the energy it delivers. There are also safety issues associated with handling and storing the gas because its combustion can be explosive. Storing hydrogen in the form of various hydride compounds, such as $LiAlH_4$, is being investigated as a means of reducing the volume and increasing the safety. One problem with this approach, however, is that such compounds have high-energy density by volume but low-energy density by mass.

▲ **Figure 22.4 Supply and demand in the hydrogen economy.** Hydrogen would need to be produced from various sources, and it would be used in energy-related applications.

Uses of Hydrogen

Hydrogen is commercially important. About half of the H_2 produced is used to synthesize ammonia by the Haber process. (Section 15.2) Much of the remaining hydrogen is used to convert high-molecular-weight hydrocarbons from petroleum into lower-molecular-weight hydrocarbons suitable for fuel (gasoline, diesel, and others) in a process known as *cracking*. Hydrogen is also used to manufacture methanol via the catalytic reaction of CO and H_2 at high pressure and temperature:

$$CO(g) + 2\,H_2(g) \longrightarrow CH_3OH(g) \qquad [22.13]$$

Binary Hydrogen Compounds

Hydrogen reacts with other elements to form three types of compounds: (1) ionic hydrides, (2) metallic hydrides, and (3) molecular hydrides.

The **ionic hydrides** are formed by the alkali metals and by the heavier alkaline earths (Ca, Sr, and Ba). These active metals are much less electronegative than hydrogen. (Figure 8.8) Consequently, hydrogen acquires electrons from them to form hydride ions (H^-):

$$Ca(s) + H_2(g) \longrightarrow CaH_2(s) \qquad [22.14]$$

The hydride ion is very basic and reacts readily with compounds having even weakly acidic protons to form H_2 as shown in **Figure 22.5** and summarized by the following equation:

$$H^-(aq) + H_2O(l) \longrightarrow H_2(g) + OH^-(aq) \qquad [22.15]$$

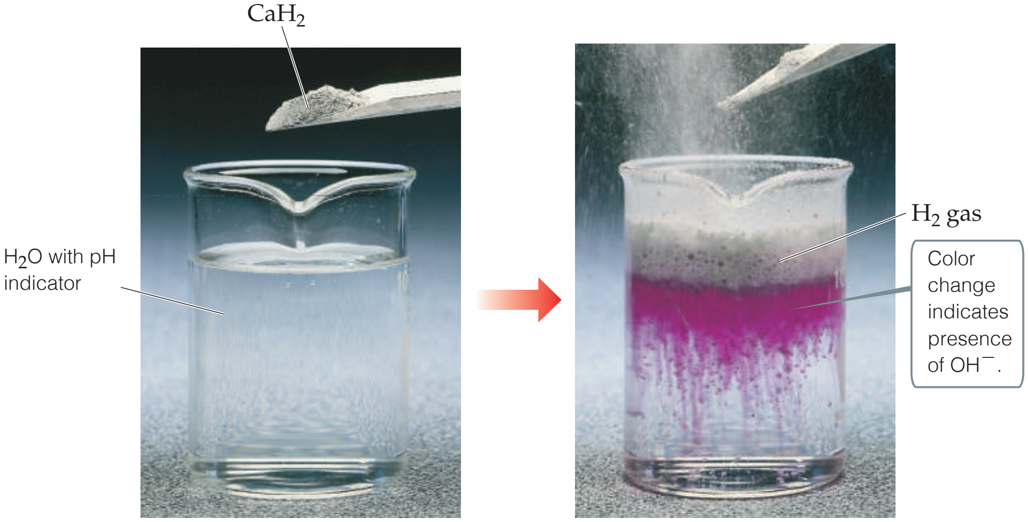
Ionic hydrides can therefore be used as convenient (although expensive) sources of H_2.

Calcium hydride (CaH_2) is used to inflate life rafts, weather balloons, and the like where a simple, compact means of generating H_2 is desired (Figure 22.5).

Metallic hydrides are formed when hydrogen reacts with transition metals. These compounds are so named because they retain their metallic properties. In many metallic hydrides, the ratio of metal atoms to hydrogen atoms is not fixed or in small whole numbers. The composition can vary within a range, depending on reaction conditions. TiH_2

Go Figure

This reaction is exothermic. Is the beaker on the right warmer or colder than the beaker on the left?



$$CaH_2(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + 2\,H_2(g)$$

▲ **Figure 22.5 The reaction of CaH_2 with water.**

can be produced, for example, but preparations usually yield $TiH_{1.8}$. These nonstoichiometric metallic hydrides are sometimes called *interstitial hydrides*. Because hydrogen atoms are small enough to fit between the sites occupied by the metal atoms, many metal hydrides behave like interstitial alloys. (Section 12.2)

The **molecular hydrides**, formed by nonmetals and metalloids, are either gases or liquids under standard conditions. The simple molecular hydrides are listed in **Figure 22.6**, together with their standard free energies of formation, ΔG_f°. (Section 19.5) In each family, the thermal stability (measured as ΔG_f°) decreases as we move down the family. (Recall that the more stable a compound is with respect to its elements under standard conditions, the more negative ΔG_f° is.)

Self-Assessment Exercises

SAE 22.6 Which of the following isotopes of hydrogen does not occur in nature? **(a)** ${}^5_1H$ **(b)** ${}^3_1H$ **(c)** ${}^2_1H$ **(d)** ${}^1_1H$

SAE 22.7 Which element would you predict reacts with hydrogen to form an ionic hydride? (**a**) C (**b**) Fe (**c**) F (**d**) Sr

SAE 22.8 Which element would you predict reacts with hydrogen to form a metallic hydride? (**a**) C (**b**) K (**c**) Fe (**d**) F

SAE 22.9 Which of the following statements is/are *true*?

(**i**) The H—H bond in hydrogen is quite strong (greater than 400 kJ/mol).
(**ii**) Atomic hydrogen, electron configuration $1s^1$, has a large ionization energy relative to lithium, electron configuration $1s^22s^1$.
(**iii**) The common oxidation states of hydrogen are −1, 0, and +1.

(**a**) Only one of the statements is true. (**b**) Only statements i and ii are true. (**c**) Only statements i and iii are true. (**d**) Only statements ii and iii are true. (**e**) All three statements are true.

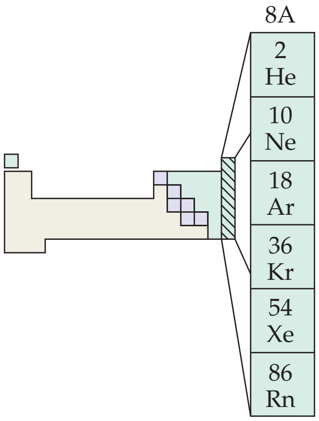
22.3 | Group 8A: The Noble Gases

Learning Objectives

When you finish Section 22.3, you should be able to:

- ▶ Predict what elements are most likely to react with noble gases.
- ▶ Determine the oxidation states of the elements in noble gas compounds.
- ▶ Predict the structures of noble-gas compounds using the VSPER model.

The elements of group 8A are chemically unreactive. Indeed, most of our references to these elements have been in relation to their physical properties, such as when we discussed intermolecular forces. (Section 11.2) The relative inertness of these elements is due to the presence of a completed octet of valence-shell electrons (except He, which only has a filled 1*s* shell). The stability of such an arrangement is reflected in the high ionization energies of the group 8A elements. (Section 7.4)



The group 8A elements are all gases at room temperature. They are components of Earth's atmosphere, except for radon, which exists only as a short-lived radioisotope. (Section 21.9) Only argon is relatively abundant. (Table 18.1)

Neon, argon, krypton, and xenon are used in lighting, display, and laser applications in which the atoms are excited electrically and electrons that are in a higher-energy state emit light as they return to the ground state. (Section 6.2) Neon signs are probably the most familiar example of noble gases used in lighting. Argon is also used as a protective atmosphere to prevent oxidation in welding and certain high-temperature metallurgical processes.

Helium is in many ways the most important noble gas. Liquid helium is used as a coolant to conduct experiments at very low temperatures. [See the "Chemistry and Sustainability" box on "Hydrogen and Helium." (Section 10.6)] Helium boils at 4.2 K and 1 atm, the lowest boiling point of any substance. It is found in relatively high concentrations in many natural-gas wells from which it is isolated.

Noble-Gas Compounds

Because the noble gases are exceedingly stable, they react only under rigorous conditions. We expect the heavier ones to be most likely to form compounds because their ionization energies are lower. (Figure 7.11) A lower ionization energy suggests the possibility of sharing an electron with another atom, leading to a chemical bond. In addition, the group 8A elements (except helium) already contain eight electrons in their valence shell, so formation of covalent bonds will require an expanded valence shell. Valence-shell expansion occurs most readily with larger atoms. (Section 8.7)

The first noble-gas compound was reported in 1962. This discovery caused a sensation because it undercut the belief that the noble-gas elements were chemically inert. The initial study involved xenon in combination with fluorine, the most electronegative element and thus the element we would expect to be most able to pull electron density from another (very polarizable) atom. Since that time, chemists have prepared several xenon compounds of fluorine and oxygen (**Table 22.1**). The fluorides XeF_2, XeF_4, and XeF_6 are made by direct reaction of the elements. By varying the ratio of reactants and altering reaction conditions, each of the three compounds can be obtained. The oxygen-containing compounds are formed when the fluorides react with water as, for example,

$$XeF_6(s) + 3\,H_2O(l) \longrightarrow XeO_3(aq) + 6\,HF(aq) \qquad [22.16]$$

The other noble-gas elements form compounds much less readily than xenon. For many years, only one binary krypton compound, KrF_2, was known with certainty, and it decomposes to its elements at −10 °C. Other compounds of krypton have been isolated at very low temperatures (40 K). In 2000, a compound of argon, HArF, was discovered, but it can exist only in argon matrices at very low temperatures. In 2017, the unusual compound Na_2He, disodium helide, was reported via reaction of the elements under high pressure, causing another sensation in the field of chemistry. In this compound the sodium atoms are partially charged cations, the He atoms bear slight negative charges, and the bulk of the negative charge to balance the Na positive charges comes from free electrons in the crystal lattice. Helium's ionization energy, 2372 kJ/mol (Figure 7.11), is the largest of the elements and thus makes He oxidation very unfavorable; thus, the usual trick of using a highly electronegative element to react with a noble gas does not work for helium.

TABLE 22.1 Properties of Xenon Compounds

Compound	Oxidation State of Xe	Melting Point (°C)	ΔH°_f (kJ/mol)[a]
XeF_2	+2	129	−109(*g*)
XeF_4	+4	117	−218(*g*)
XeF_6	+6	49	−298(*g*)
$XeOF_4$	+6	−41 to −28	+146(*l*)
XeO_3	+6	–[b]	+402(*s*)
XeO_2F_2	+6	31	+145(*s*)
XeO_4	+8	–[c]	–

[a] At 25 °C, for the compound in the state indicated.

[b] A solid; decomposes at 40 °C.

[c] A solid; decomposes at −40 °C.

Sample Exercise 22.3

Predicting a Molecular Structure

Use the VSEPR model to predict the structure of XeF_4.

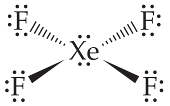
SOLUTION

Analyze We must predict the geometrical structure given only the molecular formula.

Plan We must first write the Lewis structure for the molecule. We then count the number of electron pairs (domains) around the Xe atom and use that number and the number of bonds to predict the geometry.

Solve There are 36 valence-shell electrons (8 from xenon and 7 from each fluorine). If we make four single Xe—F bonds, each fluorine has its octet satisfied. Xe then has 12 electrons in its valence shell, so we expect an octahedral arrangement of six electron pairs. Two of these are nonbonded pairs. Because nonbonded pairs require more volume than bonded pairs (Section 9.2), it is reasonable to expect these nonbonded pairs to be opposite each other. The expected structure is square planar, as shown in **Figure 22.7**.

Comment The experimentally determined structure agrees with this prediction.



▲ **Figure 22.7** **Xenon tetrafluoride.**

Practice Exercise

Describe the electron-domain geometry and molecular geometry of KrF_2.

Self-Assessment Exercises

SAE 22.10 Radon, below Xe in the periodic table, has no stable isotopes and thus is radioactive and difficult to study. Predict what type of reactions Rn is most likely to undergo. (**a**) Redox chemistry with fluorine to make radon fluorides (**b**) Redox chemistry with chlorine to make radon chlorides (**c**) Redox chemistry with calcium to make calcium radide salts (**d**) Alloys with argon at high pressure to make Ar_xRn_y compounds

SAE 22.11 What is the oxidation state of the noble gas in the compound krypton difluoride, KrF_2? (**a**) +1 (**b**) −1 (**c**) +2 (**d**) 0

SAE 22.12 The oxidation state of Xe in XeO_3 is ______ and its molecular geometry is ______. (**a**) +3, trigonal planar (**b**) +3, trigonal pyramidal (**c**) +6, trigonal planar (**d**) +6, trigonal pyramidal (**e**) +6, T-shaped

22.4 | Group 7A: The Halogens

Learning Objectives

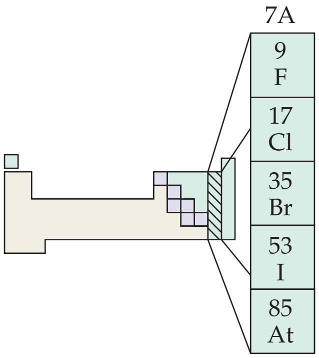
When you are finished with Section 22.4, you should be able to:

- Compare and contrast the physical and chemical properties of the halogens and their compounds.
- Predict the structure of compounds of group 7A using the VSEPR model and assign oxidation numbers to the elements within them.

The elements of group 7A, the halogens, have the outer-electron configuration ns^2np^5, where *n* ranges from 2 through 6. The halogens have large negative electron affinities (Section 7.4), and they most often achieve a noble-gas configuration by gaining an electron, which results in a −1 oxidation state. Fluorine, being the most electronegative element, exists in compounds only in the −1 state. The other halogens exhibit positive oxidation states up to +7 in combination with more electronegative atoms such as O. In the positive oxidation states, the halogens tend to be good oxidizing agents, readily accepting electrons.

Chlorine, bromine, and iodine are found as the halides in seawater and in salt deposits. Fluorine occurs in the minerals fluorspar (CaF_2), cryolite (Na_3AlF_6), and fluorapatite [$Ca_5(PO_4)_3F$].* Only fluorspar is an important commercial source of fluorine.

All isotopes of astatine are radioactive. The longest-lived isotope is astatine-210, which has a half-life of 8.1 h and decays mainly by electron capture. Because astatine is so unstable, very little is known about its chemistry.



Properties and Production of the Halogens

Most properties of the halogens vary in a regular fashion as we go from fluorine to iodine (**Table 22.2**).

Under ordinary conditions the halogens exist as diatomic molecules. The molecules are held together in the solid and liquid states by dispersion forces. (Section 11.2) Because

---

*Minerals are solid substances that occur in nature. They are usually known by their common names rather than by their chemical names. What we know as rock is merely an aggregate of different minerals.

TABLE 22.2 Some Properties of the Halogens

Property	F	Cl	Br	I
Atomic radius (Å)	0.57	1.02	1.20	1.39
Ionic radius, X^- (Å)	1.33	1.81	1.96	2.20
First ionization energy (kJ/mol)	1681	1251	1140	1008
Electron affinity (kJ/mol)	−328	−349	−325	−295

X—X single-bond enthalpy (kJ/mol)	155	242	193	151
Reduction potential (V):				
$\frac{1}{2}X_2(aq) + e^- \longrightarrow X^-(aq)$	2.87	1.36	1.07	0.54

I_2 is the largest and most polarizable halogen molecule, the intermolecular forces between I_2 molecules are the strongest. Thus, I_2 has the highest melting point and boiling point. At room temperature and 1 atm, I_2 is a purple solid, Br_2 is a red-brown liquid, and Cl_2 and F_2 are gases. (Figure 7.28) Chlorine readily liquefies upon compression at room temperature and is normally stored and handled in liquid form under pressure in steel containers.

The comparatively low bond enthalpy of F_2 (155 kJ/mol) accounts in part for the extreme reactivity of elemental fluorine. Because of its high reactivity, F_2 is difficult to work with. Certain metals, such as copper and nickel, can be used to contain F_2 because their surfaces form a protective coating of metal fluoride. Chlorine and the heavier halogens are also reactive, though less so than fluorine.

Because of their high electronegativities, the halogens tend to gain electrons from other substances and thereby serve as oxidizing agents. The oxidizing ability of the halogens, indicated by their standard reduction potentials, decreases going down the group. As a result, a given halogen is able to oxidize the halide anions below it. For example, Cl_2 oxidizes Br^- and I^- but not F^-, as seen in **Figure 22.8**.

Notice in Table 22.2 that the standard reduction potential of F_2 is exceptionally high. As a result, fluorine gas readily oxidizes water:

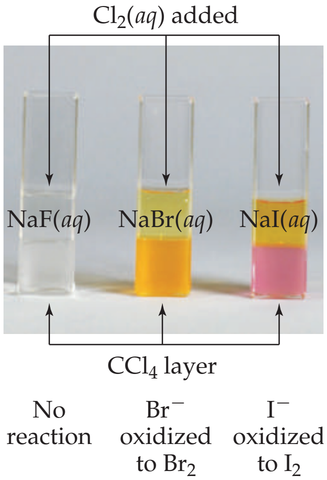
$$F_2(aq) + H_2O(l) \longrightarrow 2\,HF(aq) + \tfrac{1}{2}O_2(g) \quad E^\circ = 1.80\text{ V} \qquad [22.17]$$

Fluorine cannot be prepared by electrolytic oxidation of aqueous solutions of fluoride salts because water is oxidized more readily than F^-. (Section 20.9) In practice, the element is formed by electrolytic oxidation of a solution of KF in anhydrous HF.

Chlorine is produced mainly by electrolysis of either molten or aqueous sodium chloride. Both bromine and iodine are obtained commercially from brines containing the halide ions; the reaction used is oxidation with Cl_2.

Go Figure

Do Br_5 and I_2 appear to be more or less soluble in CCl_4 than in H_2O?



▲ **Figure 22.8 Reaction of Cl_2 with aqueous solutions of NaF, NaBr, and NaI in the presence of carbon tetrachloride.** The top liquid layer in each vial is water; the bottom liquid layer is carbon tetrachloride. The $Cl_2(aq)$, which has been added to each vial, is colorless. The brown color in the carbon tetrachloride layer indicates the presence of Br_2, whereas purple indicates the presence of I_2.

Sample Exercise 22.4

Predicting Chemical Reactions among the Halogens

Write the balanced equation for the reaction, if any, between (**a**) $I^-(aq)$ and $Br_2(l)$, (**b**) $Cl^-(aq)$ and $I_2(s)$.

SOLUTION

Analyze We are asked to determine whether a reaction occurs when a particular halide and halogen are combined.

Plan A given halogen is able to oxidize anions of the halogens below it in the periodic table. Thus, in each pair the halogen having the smaller atomic number ends up as the halide ion. If the halogen with the smaller atomic number is already the halide ion, there is no reaction. Thus, the key to determining whether a reaction occurs is locating the elements in the periodic table.

Solve

(**a**) Br_2 can oxidize (remove electrons from) the anions of the halogens below it in the periodic table. Thus, it oxidizes I^-:

$$2\,I^-(aq) + Br_2(aq) \longrightarrow I_2(s) + 2\,Br^-(aq)$$

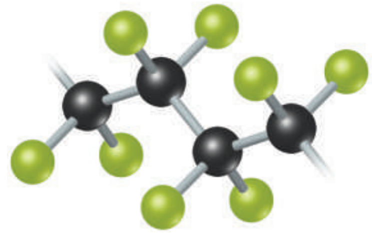
(**b**) Cl^- is the anion of a halogen above iodine in the periodic table. Thus, I_2 cannot oxidize Cl^-; there is no reaction.

Practice Exercise

Write the balanced chemical equation for the reaction between $Br^-(aq)$ and $Cl_2(aq)$.

Go Figure

What is the repeating unit in this polymer?



▲ **Figure 22.9** **Structure of Teflon®, a fluorocarbon polymer.**

Uses of the Halogens

Fluorine is used to prepare fluorocarbons—very stable carbon–fluorine compounds used as refrigerants, lubricants, and plastics. Teflon® (**Figure 22.9**) is a polymeric fluorocarbon noted for its high thermal stability and lack of chemical reactivity.

Chlorine is by far the most commercially important halogen. About half of the chlorine is used to manufacture chlorine-containing organic compounds, such as the vinyl chloride (C_2H_3Cl) used in making polyvinyl chloride (PVC) plastics. (Section 12.6) Much of the remainder is used as a bleaching agent in the paper and textile industries.

When Cl_2 dissolves in cold dilute base, it converts into Cl^- and hypochlorite, ClO^-:

$$Cl_2(aq) + 2\,OH^-(aq) \rightleftharpoons Cl^-(aq) + ClO^-(aq) + H_2O(l) \qquad [22.18]$$

Sodium hypochlorite (NaClO) is the active ingredient in many liquid bleaches. Chlorine is also used in water treatment to oxidize and thereby destroy bacteria. (Section 18.4)

A common use of iodine is as KI in table salt. Iodized salt provides the small amount of iodine necessary in our diets; it is essential for the formation of thyroxin, a hormone secreted by the thyroid gland. Lack of iodine in the diet results in an enlarged thyroid gland, a condition called *goiter*.

The Hydrogen Halides

All the halogens form stable diatomic molecules with hydrogen. The hydrogen halides can be formed by direct reaction of the elements.

The hydrogen halides form hydrohalic acid solutions when dissolved in water. These solutions have the characteristic properties of acids, such as reactions with active metals to produce hydrogen gas. (Section 4.4) Hydrofluoric acid also reacts readily with **silica** (SiO_2) and with silicates to form hexafluorosilicic acid (H_2SiF_6):

$$SiO_2(s) + 6\,HF(aq) \longrightarrow H_2SiF_6(aq) + 2\,H_2O(l) \qquad [22.19]$$

Interhalogen Compounds

Because the halogens exist as diatomic molecules, diatomic molecules made up of two different halogen atoms exist. These compounds are the simplest examples of **interhalogens**, compounds, such as ClF and IF_5, formed between two halogen elements.

The vast majority of the higher interhalogen compounds have a central Cl, Br, or I atom surrounded by fluorine atoms. The large size of the iodine atom allows the formation of IF_3, IF_5, and IF_7, in which the oxidation state of I is +3, +5, and +7, respectively. With the smaller bromine and chlorine atoms, only compounds with three or five fluorines form. The only higher interhalogen compounds that do not have outer F atoms are ICl_3 and ICl_5; the large size of the I atom can accommodate five Cl atoms, whereas Br is not large enough to allow even $BrCl_3$ to form. All of the interhalogen compounds are powerful oxidizing agents.

Oxyacids and Oxyanions

Table 22.3 summarizes the formulas of the known oxyacids of the halogens and the way they are named.* (Section 2.8) The acid strengths of the oxyacids increase with the increasing oxidation state of the central halogen atom. (Section 16.10) All the oxyacids are strong oxidizing agents. The oxyanions, formed on removal of H^+ from the oxyacids, are generally more stable than the oxyacids. Hypochlorite salts are used as bleaches and disinfectants because of the powerful oxidizing capabilities of the ClO^- ion. Chlorate salts are similarly very reactive. For example, potassium chlorate is used to make matches and fireworks.

---

*Fluorine forms one oxyacid, HOF. Because the electronegativity of fluorine is greater than that of oxygen, we must consider fluorine to be in a −1 oxidation state and oxygen to be in the 0 oxidation state in this compound.

TABLE 22.3 The Stable Oxyacids of the Halogens

	Formula of Acid			
Oxidation State of Halogen	Cl	Br	I	Acid Name
+1	HClO	HBrO	HIO	*Hypo*halous acid
+3	$HClO_2$	—	—	Hal*ous* acid
+5	$HClO_3$	$HBrO_3$	HIO_3	Hal*ic* acid
+7	$HClO_4$	$HBrO_4$	HIO_4	*Per*hal*ic* acid

Perchloric acid and its salts are the most stable oxyacids and oxyanions. Dilute solutions of perchloric acid are quite safe, and many perchlorate salts are stable except when heated with organic materials. When heated, however, perchlorates can become vigorous, even violent, oxidizers. Considerable caution should be exercised, therefore, when handling these substances, and it is crucial to avoid contact between perchlorates and readily oxidized material. The use of ammonium perchlorate (NH_4ClO_4) as the oxidizer in the solid booster rockets for space vehicle launches demonstrates the oxidizing power of perchlorates. The solid propellant contains a mixture of NH_4ClO_4 and powdered aluminum, the reducing agent. Each launch requires about 6×10^5 kg (700 tons) of NH_4ClO_4 (**Figure 22.10**).

$$10\,Al(s) + 6\,NH_4ClO_4(s) \longrightarrow 4\,Al_2O_3(s) + 2\,AlCl_3(s) + 12\,H_2O(g) + 3\,N_2(g)$$

The large volume of gases produced provides thrust for the booster rockets.

▲ **Figure 22.10 Launch of the Space Shuttle *Columbia* from the Kennedy Space Center.**

SAE 22.13 The smallest halogen is ______, and the easiest halogen to oxidize is ______. (**a**) fluorine, fluorine (**b**) fluorine, iodine (**c**) iodine, fluorine (**d**) iodine, iodine

SAE 22.14 The oxidation number of iodine in IF_3 is ______ and its molecular geometry is ______. (**a**) +3, trigonal (**b**) +3, T-shaped (**c**) +3, trigonal pyramidal (**d**) +3, trigonal bipyramidal (**e**) −3, trigonal pyramidal

22.5 | Oxygen

Oxygen is found in combination with other elements in a great variety of compounds; water (H_2O), silica (SiO_2), alumina (Al_2O_3), and the iron oxides (Fe_2O_3, Fe_3O_4) are common examples. Indeed, oxygen is the most abundant element by mass both in Earth's crust and in the human body. (Section 1.2) It is the oxidizing agent for the metabolism of our foods and is crucial to human life.

Learning Objectives

When you finish Section 22.5, you should be able to:

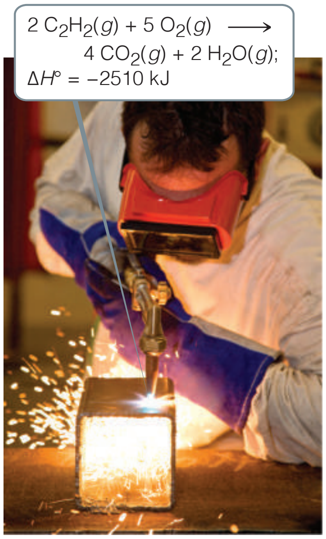
- Write balanced chemical equations for reactions involving oxygen.
- Compare the acid–base properties of metal oxides and nonmetal oxides.
- Assign oxidation states to oxygen atoms in reactive oxygen species.

Properties of Oxygen

Oxygen has two allotropes, O_2 and O_3. When we speak of molecular oxygen or simply oxygen, it is usually understood that we are speaking of *dioxygen* (O_2), the normal form of the element; O_3 is ozone.

At room temperature, dioxygen is a colorless and odorless gas. Dioxygen is only slightly soluble in water (0.04 g/L, or 0.001 *M* at 25 °C), but its presence in water is essential to marine life.

The electron configuration of the oxygen atom is $[He]2s^22p^4$. Thus, oxygen can complete its octet of valence electrons either by picking up two electrons to form the oxide ion (O^{2-}) or by sharing two electrons. In its covalent compounds, it tends to form either two single bonds, as in H_2O, or a double bond, as in formaldehyde ($H_2C{=}O$). The O_2 molecule contains a double bond. The bond in O_2 is very strong (bond enthalpy 495 kJ/mol). Oxygen also forms strong bonds with many other elements. Consequently, many oxygen-containing compounds are thermodynamically more stable than O_2. In the absence of a catalyst, however, most reactions of O_2 have high activation energies and thus require high temperatures to proceed at a suitable rate. Once a sufficiently exothermic reaction begins, it may accelerate rapidly, producing a reaction of explosive violence.



$2\,C_2H_2(g) + 5\,O_2(g) \longrightarrow 4\,CO_2(g) + 2\,H_2O(g)$; $\Delta H^\circ = -2510\text{ kJ}$

▲ **Figure 22.11 Welding with an oxyacetylene torch.**

Production of Oxygen

Nearly all commercial oxygen is obtained from air. The normal boiling point of O_2 is −183 °C, whereas that of N_2, the other principal component of air, is −196 °C. Thus, when air is liquefied and then allowed to warm, the N_2 boils off, leaving liquid O_2 contaminated mainly by small amounts of N_2 and Ar.

Much of the O_2 in the atmosphere is replenished through photosynthesis, in which green plants use the energy of sunlight to generate O_2 (along with glucose, $C_6H_{12}O_6$) from atmospheric CO_2:

$$6\,CO_2(g) + 6\,H_2O(l) \longrightarrow C_6H_{12}O_6(aq) + 6\,O_2(g) \qquad [22.20]$$

Uses of Oxygen

In industrial use, oxygen ranks behind only sulfuric acid (H_2SO_4) and nitrogen (N_2). Oxygen is by far the most widely used oxidizing agent in industry. Over half of the O_2 produced is used in the steel industry, mainly to remove impurities from steel. It is also used to bleach pulp and paper. (Oxidation of colored compounds often gives colorless products.) Oxygen is used together with acetylene (C_2H_2) in oxyacetylene welding (**Figure 22.11**). The reaction between C_2H_2 and O_2 is highly exothermic, producing temperatures in excess of 3000 °C.

Ozone

Ozone is a pale blue, poisonous gas with a sharp, irritating odor. Many people can detect as little as 0.01 ppm in air. Exposure to 0.1 to 1 ppm produces headaches, burning eyes, and irritation to the respiratory passages.

The O_3 molecule possesses π electrons that are delocalized over the three oxygen atoms. (Section 8.6) The molecule dissociates readily, forming reactive oxygen atoms:

$$O_3(g) \longrightarrow O_2(g) + O(g) \quad \Delta H^\circ = 105\text{ kJ} \qquad [22.21]$$

Ozone is a stronger oxidizing agent than dioxygen. Ozone forms oxides with many elements under conditions where O_2 will not react; indeed, it oxidizes all the common metals except gold and platinum.

Ozone can be prepared by passing electricity through dry O_2. During thunderstorms, ozone is generated (and can be smelled, if you are too close) from lightning strikes:

$$3\,O_2(g) \xrightarrow{\text{electricity}} 2\,O_3(g) \quad \Delta H^\circ = 284.6\text{ kJ} \qquad [22.22]$$

Ozone is sometimes used to treat drinking water. Like Cl_2, ozone kills bacteria and oxidizes organic compounds. The largest use of ozone, however, is in the preparation of pharmaceuticals, synthetic lubricants, and other commercially useful organic compounds, where O_3 is used to sever carbon–carbon double bonds.

Ozone is an important component of the upper atmosphere, where it screens out ultraviolet radiation and so protects us from the effects of these high-energy rays. For this reason, depletion of stratospheric ozone is a major scientific concern. (Section 18.2) In the lower atmosphere, ozone is considered an air pollutant and is a major constituent of smog. (Section 18.2) Because of its oxidizing power, ozone damages living systems and structural materials, especially rubber.

Oxides

The electronegativity of oxygen is second only to that of fluorine. As a result, oxygen has negative oxidation states in all compounds except OF_2 and O_2F_2. The −2 oxidation state is by far the most common. Compounds that contain oxygen in this oxidation state are called *oxides*.

Nonmetals form covalent oxides, most of which are simple molecules with low melting and boiling points. Both SiO_2 and B_2O_3, however, have extended structures. Most nonmetal oxides combine with water to give oxyacids. Sulfur dioxide (SO_2), for example, dissolves in water to give sulfurous acid (H_2SO_3):

$$SO_2(g) + H_2O(l) \longrightarrow H_2SO_3(aq) \qquad [22.23]$$

This reaction and that of SO_3 with H_2O to form H_2SO_4 are largely responsible for acid rain. (Section 18.2) The analogous reaction of CO_2 with H_2O to form carbonic acid (H_2CO_3) causes the acidity of carbonated water.

Oxides that form acids when they react with water are called either **acidic anhydrides** (anhydride means "without water") or **acidic oxides**. A few nonmetal oxides, especially ones with the nonmetal in a low oxidation state—such as N_2O, NO, and CO—do not react with water and are not acidic anhydrides.

Most metal oxides are ionic compounds. The ionic oxides that dissolve in water form hydroxides and, consequently, are called either **basic anhydrides** or **basic oxides**. Barium oxide, for example, reacts with water to form barium hydroxide (**Figure 22.12**). These kinds of reactions are due to the high basicity of the O^{2-} ion and its virtually complete hydrolysis in water:

$$O^{2-}(aq) + H_2O(l) \longrightarrow 2\,OH^-(aq) \qquad [22.24]$$

Even those ionic oxides that are insoluble in water tend to dissolve in strong acids. Iron(III) oxide, for example, dissolves in acids:

$$Fe_2O_3(s) + 6\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + 3\,H_2O(l) \qquad [22.25]$$

This reaction is used to remove rust ($Fe_2O_3 \cdot nH_2O$) from iron or steel before a protective coat of zinc or tin is applied.

Oxides that can exhibit both acidic and basic characters are said to be *amphoteric*. (Section 17.5) If a metal forms more than one oxide, the basic character of the oxide decreases as the oxidation state of the metal increases (**Table 22.4**); or said a different way, the higher the oxidation state of the metal, the more acidic the oxide. The reasons for this are complex, but it comes down to M—O bonding in the oxide.

Go Figure Is this reaction a redox reaction?

$$2\,OH^-(aq) + CO_2(g\text{, from breath}) \longrightarrow H_2O(l) + CO_3^{2-}(aq)$$

▲ **Figure 22.13 A self-contained breathing apparatus.**

TABLE 22.4 Acid–Base Character of Chromium Oxides

Oxide	Oxidation State of Cr	Nature of Oxide
CrO	+2	Basic
Cr_2O_3	+3	Amphoteric
CrO_3	+6	Acidic

Lower-oxidation-state metals (CrO in Table 22.4) have more ionic M—O bonds, and thus react with water to produce hydroxide (Figure 22.12). Higher-oxidation-state metals in metal oxides (CrO_3 in Table 22.4) have more covalent M—O bonding, are more acidic and thus react with hydroxide to produce water:

$$CrO_3(s) + 2\,OH^-(aq) \longrightarrow CrO_4^{2-}(aq) + H_2O(l) \qquad [22.26]$$

Peroxides, Superoxides and Reactive Oxygen Species

Compounds containing O—O bonds and oxygen in the −1 oxidation state are *peroxides*. Oxygen has an oxidation state of $-\frac{1}{2}$ in O_2^-, which is called the *superoxide* ion. The most active (easily oxidized) metals (K, Rb, and Cs) react with O_2 to give superoxides (KO_2, RbO_2, and CsO_2). Their active neighbors in the periodic table (Na, Ca, Sr, and Ba) react with O_2, producing peroxides (Na_2O_2, CaO_2, SrO_2, and BaO_2). Less active metals and nonmetals produce normal oxides. (Section 7.5)

When superoxides dissolve in water, O_2 is produced:

$$4\,KO_2(s) + 2\,H_2O(l) \longrightarrow 4\,K^+(aq) + 4\,OH^-(aq) + 3\,O_2(g) \qquad [22.27]$$

Because of this reaction, potassium superoxide is used as an oxygen source in masks worn by rescue workers (**Figure 22.13**). For proper breathing in toxic environments, oxygen must be generated in the mask and exhaled carbon dioxide in the mask must be eliminated. Moisture in the breath causes the KO_2 to decompose to O_2 and KOH, and the KOH removes CO_2 from the exhaled breath:

$$2\,OH^-(aq) + CO_2(g) \longrightarrow H_2O(l) + CO_3^{2-}(aq) \qquad [22.28]$$

Hydrogen peroxide (**Figure 22.14**) is the most familiar and commercially important peroxide. Pure hydrogen peroxide is a clear, syrupy liquid that melts at −0.4 °C. Concentrated hydrogen peroxide is dangerously reactive because the decomposition to water and oxygen is very exothermic:

$$2\,H_2O_2(l) \longrightarrow 2\,H_2O(l) + O_2(g) \quad \Delta H^\circ = -196.1\text{ kJ} \qquad [22.29]$$

This is an example of a **disproportionation** reaction, in which an element is simultaneously oxidized and reduced. The oxidation number of oxygen changes from −1 to −2 and 0.

Hydrogen peroxide is marketed as a chemical reagent in aqueous solutions of up to about 30% by mass. A solution containing about 3% H_2O_2 by mass is sold in drugstores and used as a mild antiseptic. Somewhat more concentrated solutions are used to bleach fabrics.

The peroxide ion is a byproduct of metabolism that results from the reduction of O_2. Peroxide, superoxide, and similar O-containing compounds that are byproducts of metabolism are called **reactive oxygen species** (ROS). Some ROS is always present in living systems. Elevated levels of ROS in biological systems are associated with stress, and can lead to oxidation of key compounds such as proteins and DNA, leading to irreversible oxidative damage and potentially disease. To counteract these reactions, the body has numerous enzymes that catalyze the destruction of ROS. *Superoxide dismutase*, for example, catalyzes the conversion of superoxide into oxygen and hydrogen peroxide. *Catalase* catalyzes the decomposition of hydrogen peroxide into water and oxygen, the same reaction as Equation 22.29.

SAE 22.17 The hydroxyl radical, OH·, called "O–H dot," is another example of a reactive oxygen species. Two hydroxy radicals would be formed if the O—O bond in hydrogen peroxide was cut in half. How many valence electrons does one hydroxyl radical contain? **(a)** 6 **(b)** 7 **(c)** 8 **(d)** 9 **(e)** 10

22.6 The Other Group 6A Elements: S, Se, Te, and Po

The other group 6A elements are sulfur, selenium, tellurium, and polonium. Of these, sulfur is the most important, and polonium, which has no stable isotopes and is found only in minute quantities in radium-containing minerals, is least important.

The group 6A elements possess the general outer-electron configuration ns^2np^4 with n ranging from 2 to 6. Thus, these elements attain a noble-gas electron configuration by adding two electrons, which results in a −2 oxidation state. Except for oxygen, the group 6A elements are also commonly found in positive oxidation states up to +6, and they can have expanded valence shells. Thus, we have such compounds as SF_6, SeF_6, and TeF_6 with the central atom in the +6 oxidation state.

Table 22.5 summarizes some properties of the group 6A elements.

Learning Objectives

When you are finished with Section 22.6, you should be able to:

- Predict the physical and chemical properties of the group 6A elements beyond oxygen.
- Predict the structure of compounds of group 6A using the VSEPR model and assign oxidation numbers to the elements within them.

Occurrence and Production of S, Se, and Te

Sulfur, selenium, and tellurium can all be mined from the earth. Large underground deposits are the principal source of elemental sulfur (**Figure 22.15**). Sulfur also occurs widely as sulfide (S^{2-}) and sulfate (SO_4^{2-}) minerals. Its presence as a minor component of coal and petroleum poses a major problem. Combustion of these "unclean" fuels leads to serious pollution by sulfur oxides. (Section 18.2) Much effort has been directed at removing this sulfur, and these efforts have increased the availability of sulfur.

Selenium and tellurium occur in rare minerals, such as Cu_2Se, PbSe, Cu_2Te, and PbTe, and as minor constituents in sulfide ores of copper, iron, nickel, and lead.

Properties and Uses of Sulfur, Selenium, and Tellurium

Elemental sulfur is yellow, tasteless, and nearly odorless. It is insoluble in water and exists in several allotropic forms. The thermodynamically stable form at room temperature is

TABLE 22.5 Some Properties of the Group 6A Elements

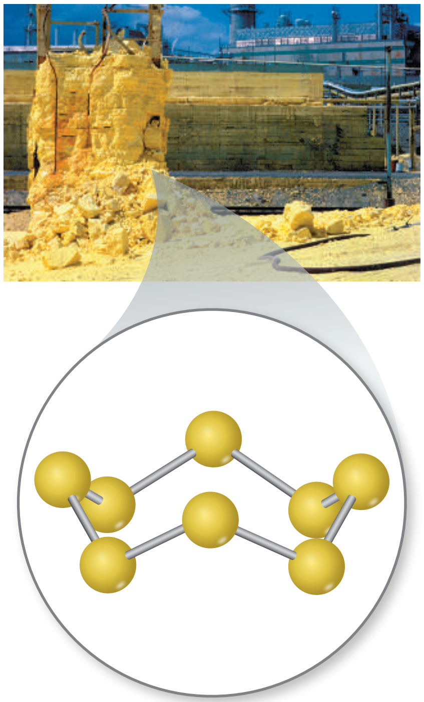
rhombic sulfur, which consists of puckered S_8 rings with each sulfur atom forming two bonds (Figure 22.15).



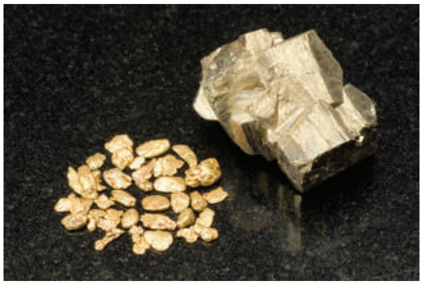
▲ **Figure 22.15** **Massive amounts of sulfur are extracted every year from the earth.**

Most of the sulfur produced in the United States each year is used to manufacture sulfuric acid. Sulfur is also used to vulcanize rubber, a process that toughens rubber by introducing cross-linking between polymer chains. (Section 12.6)

Selenium is used in photoelectric cells and light meters because its electrical conductivity increases greatly upon exposure to light. Photocopiers also depend on the photoconductivity of selenium. Photocopy machines contain a belt or drum coated with a film of selenium. This drum is electrostatically charged and then exposed to light reflected from the image being photocopied. The charge drains from the regions where the selenium film has been made conductive by exposure to light. A black powder (the toner) sticks only to the areas that remain charged. The photocopy is made when the toner is transferred to a sheet of plain paper.

Sulfides

When an element is less electronegative than sulfur, *sulfides* that contain S^{2-} form. Many metallic elements are found in the form of sulfide ores, such as PbS (galena) and HgS (cinnabar). A series of related ores containing the disulfide ion, S_2^{2-} (analogous to the peroxide ion), are known as *pyrites*. Iron pyrite, FeS_2, occurs as golden yellow cubic crystals (**Figure 22.16**). Because it has been occasionally mistaken for gold by miners, iron pyrite is often called fool's gold.



▲ **Figure 22.16** **Iron pyrite (FeS_2, on the right) with gold for comparison.**

One of the most important sulfides is hydrogen sulfide (H_2S). One of hydrogen sulfide's most readily recognized properties is its odor, which is most frequently encountered as the offensive odor of rotten eggs. Hydrogen sulfide is toxic, but our noses can detect H_2S in extremely low, nontoxic concentrations. A sulfur-containing organic molecule, such as dimethyl sulfide, $(CH_3)_2S$, which is similarly odoriferous and can be detected by smell at a level of one part per trillion, is added to natural gas as a safety factor to give it a detectable odor.

Oxides, Oxyacids, and Oxyanions of Sulfur

Sulfur dioxide, formed when sulfur burns in air, has a choking odor and is poisonous. The gas is particularly toxic to lower organisms, such as fungi, so it is used to sterilize dried fruit and wine. At 1 atm and room temperature, SO_2 dissolves in water to produce a 1.6 M solution. The SO_2 solution is acidic, and we describe it as sulfurous acid (H_2SO_3).

Salts of SO_3^{2-} (sulfites) and HSO_3^- (hydrogen sulfites or bisulfites) are well known. Small quantities of Na_2SO_3 or $NaHSO_3$ are used as food additives to prevent bacterial spoilage. However, they are known to increase asthma symptoms in approximately 5% of asthmatics. Thus, all food products with sulfites must now carry a warning label disclosing their presence (**Figure 22.17**).

CONTAINS SULFITES
VALENCIA
DENOMINACION DE ORIGEN
649069

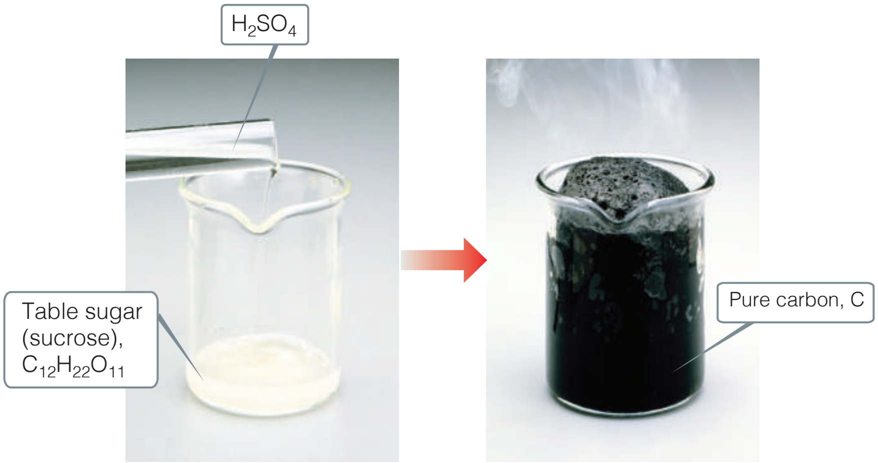
▲ **Figure 22.17** **Food label warning of sulfites.**

Although combustion of sulfur in air produces mainly SO_2, small amounts of SO_3 are also formed. The reaction produces chiefly SO_2 because the activation-energy barrier for oxidation to SO_3 is very high unless the reaction is catalyzed. Interestingly, the SO_3 by-product is used industrially to make H_2SO_4, which is the ultimate product of the reaction between SO_3 and water. In the manufacture of sulfuric acid, SO_2 is obtained by burning sulfur and then is oxidized to SO_3, using a catalyst such as V_2O_5 or platinum. The SO_3 is dissolved in H_2SO_4 because it does not dissolve quickly in water, and then the $H_2S_2O_7$ formed in this reaction, called pyrosulfuric acid, is added to water to form H_2SO_4:

$$SO_3(g) + H_2SO_4(l) \longrightarrow H_2S_2O_7(l) \qquad [22.30]$$

$$H_2S_2O_7(l) + H_2O(l) \longrightarrow 2\,H_2SO_4(l) \qquad [22.31]$$

Commercial sulfuric acid is 98% H_2SO_4. It is a dense, colorless, oily liquid. It is a strong acid, a good dehydrating agent (**Figure 22.18**), and a moderately good oxidizing agent.



$$C_{12}H_{22}O_{11}(s) \xrightarrow{H_2SO_4(aq)} 12\ C(s) + 11\ H_2O(l)$$

▲ **Figure 22.18** **Sulfuric acid dehydrates table sugar to produce elemental carbon.**

Year after year, the production of sulfuric acid is the largest of any chemical produced in the United States. It is employed in some way in almost all manufacturing.

Sulfuric acid is a strong acid, but only the first hydrogen is completely ionized in aqueous solution:

$$H_2SO_4(aq) \longrightarrow H^+(aq) + HSO_4^-(aq) \qquad [22.32]$$

$$HSO_4^-(aq) \rightleftharpoons H^+(aq) + SO_4^{2-}(aq) \quad K_a = 1.1 \times 10^{-2} \qquad [22.33]$$

Consequently, sulfuric acid forms both sulfates (SO_4^{2-} salts) and bisulfates (or hydrogen sulfates, HSO_4^- salts). Bisulfate salts are common components of the "dry acids" used for adjusting the pH of swimming pools and hot tubs; they are also components of many toilet bowl cleaners.

Another important sulfur-containing ion is thiosulfate ion ($S_2O_3^{2-}$). The term *thio* indicates substitution of sulfur for oxygen. The structures of the sulfate and thiosulfate ions are compared in **Figure 22.19**.

Thiols, organic compounds with a —SH group bonded to carbon, play important roles in biology. When thiols are oxidized under mild conditions, they form disulfides, organic compounds with S—S bonds between carbon atoms that are analogous to peroxides. In the opposite fashion, disulfide bonds can be broken by reducing them to thiols. The shape and function of proteins can be modified by forming or breaking disulfide bonds between protein strands. Many proteins maintain their three-dimensional shape due to S–S crosslinks. Hair-straightening and curling technologies rely on the breaking and re-forming of disulfide bonds between the protein molecules of hair (**Figure 22.20**).

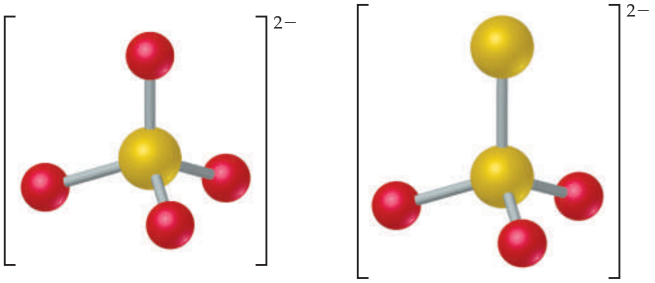
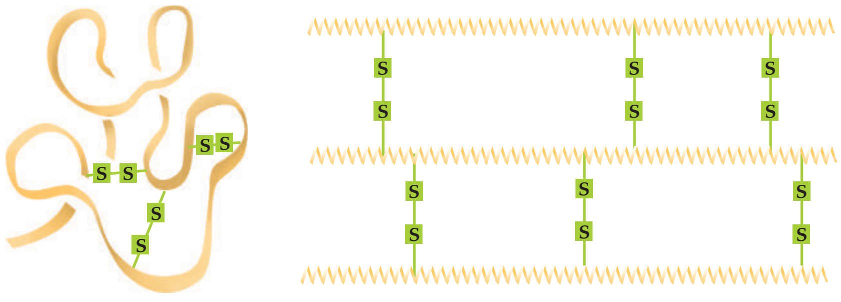
What are the oxidation states of the sulfur atoms in the $S_2O_3^{2-}$ ion?



▲ **Figure 22.19** **Structures of the sulfate (left) and thiosulfate (right) ions.**



Curly hair **Straight hair**

▲ **Figure 22.20** **Hair straightening and curling.** People can alter the shape of their hair by first applying a reducing agent that breaks the disulfide bonds between protein strands. The hair is given its desired shape, and then an oxidizing agent is added to form new disulfide bonds to maintain the shape.

Self-Assessment Exercises

SAE 22.18 What is the chemical formula for sulfurous acid? What is the oxidation state of sulfur in this compound? (**a**) H_2SO_3, +6 (**b**) HSO_3, +5 (**c**) H_2SO_3, +4 (**d**) H_2S, −2

SAE 22.19 Predict the molecular structure of sulfur tetrachloride, SCl_4. (**a**) square pyramidal (**b**) see-saw (**c**) linear (**d**) square-planar

SAE 22.20 Which of the following reactions best describes the reaction between hydrogen peroxide and selenium?

(**a**) $2\,H_2O_2(aq) + Se(s) \longrightarrow SeO_2(s) + 2\,H_2O(l)$
(**b**) $H_2O_2(aq) + Se(s) \longrightarrow SeO_2(s) + H_2O(l)$
(**c**) $H_2O_2(aq) + Se(s) \longrightarrow SeO_2(s) + 2\,H_2O(l)$
(**d**) $H_2O_2(aq) + Se(s) \longrightarrow SeO_2(s) + H_2(g)$

SAE 22.21 For the reaction $RSH + HSR' \longrightarrow RSSR' + H_2$, where R and R′ are alkyl groups, what are the oxidation states of sulfur in the reactants and products, respectively? (**a**) 0, 0 (**b**) −1, −1 (**c**) −2, −2 (**d**) −2, −1 (**e**) −1, −2

22.7 | Nitrogen

Learning Objectives

When you finish Section 22.7, you should be able to:

- ▶ Determine the oxidation state of nitrogen in compounds.
- ▶ Write balanced chemical equations for reactions of nitrogen-containing compounds.

Nitrogen constitutes 78% by volume of Earth's atmosphere, where it occurs as N_2 molecules. Although nitrogen is a key element in living organisms, compounds of nitrogen are not abundant in Earth's crust. The major natural deposits of nitrogen compounds are those of KNO_3 (saltpeter) in India and $NaNO_3$ (Chile saltpeter) in Chile and other desert regions of South America.

Properties of Nitrogen

Nitrogen is a colorless, odorless, tasteless gas composed of N_2 molecules. The N_2 molecule is very unreactive because of the strong triple bond between nitrogen atoms (the $N\equiv N$ bond enthalpy is 941 kJ/mol, nearly twice that for the bond in O_2.) (Table 8.3) When substances burn in air, they normally react with O_2 but not with N_2.

The electron configuration of the nitrogen atom is $[He]2s^22p^3$. The element exhibits all formal oxidation states from +5 to −3 (**Table 22.6**). The +5, 0, and −3 oxidation states are the most common and generally the most stable of these. Because nitrogen is more electronegative than all other elements except fluorine, oxygen, and chlorine, it exhibits positive oxidation states only in combination with these three elements.

TABLE 22.6 **Oxidation States of Nitrogen**

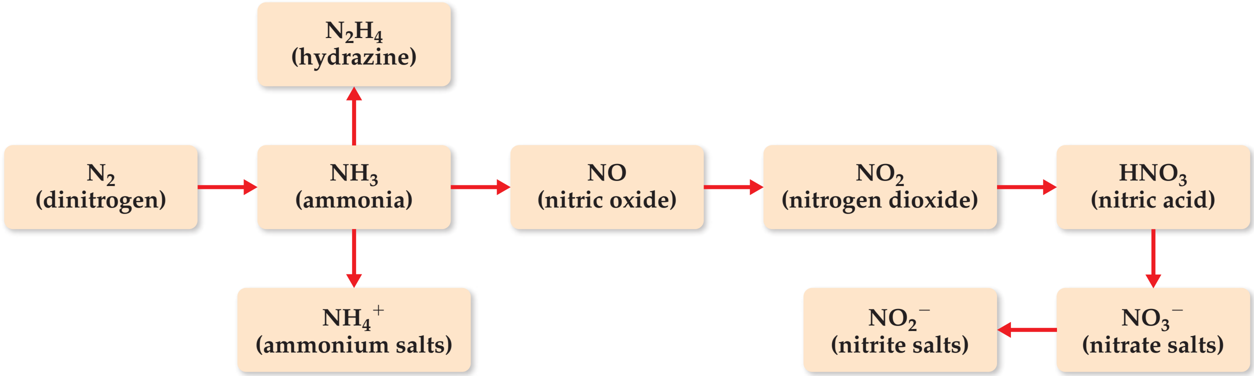
Oxidation State	Examples
+5	N_2O_5, HNO_3, NO_3^-
+4	NO_2, N_2O_4
+3	HNO_2, NO_2^-, NF_3
+2	NO
+1	N_2O, $H_2N_2O_2$, $N_2O_2^{2-}$, HNF_2
0	N_2
−1	NH_2OH, NH_2F
−2	N_2H_4
−3	NH_3, NH_4^+, NH_2^-

Production and Uses of Nitrogen

Elemental nitrogen is obtained in commercial quantities by fractional distillation of liquid air. Because of its low reactivity, large quantities of N_2 are used as an inert gaseous blanket to exclude O_2 in food processing, manufacture of chemicals, metal fabrication, and production of electronic devices. Liquid N_2 is employed as a coolant to freeze foods rapidly.

The largest use of N_2 is in the manufacture of nitrogen-containing fertilizers. These fertilizers provide a source of *fixed* nitrogen—nitrogen that has been incorporated into compounds. We have previously discussed nitrogen fixation in the "Chemistry and Life" box on "Nitrogen Fixation and Nitrogenase" in Section 14.6 and in the "Chemistry and Sustainability" box on "The Haber Process: Feeding the World" in Section 15.2. Our

Go Figure In which of these species is the oxidation number of nitrogen +3?



▲ **Figure 22.21** **Sequence of conversion of N_2 into common nitrogen compounds.**

starting point in fixing nitrogen is the manufacture of ammonia via the Haber process. (Section 15.2) The ammonia can then be converted into a variety of useful, simple nitrogen-containing species (**Figure 22.21**).

Hydrogen Compounds of Nitrogen

Ammonia is one of the most important compounds of nitrogen. It is a colorless, toxic gas that has a characteristic irritating odor. As noted in previous discussions, the NH_3 molecule is basic ($K_b = 1.8 \times 10^{-5}$). (Section 16.7)

In the laboratory, NH_3 can be prepared by the action of NaOH on an ammonium salt. The NH_4^+ ion, which is the conjugate acid of NH_3, transfers a proton to OH^-. The resultant NH_3 is volatile and is driven from the solution by mild heating:

$$NH_4Cl(aq) + NaOH(aq) \longrightarrow NH_3(g) + H_2O(l) + NaCl(aq) \qquad [22.34]$$

Commercial production of NH_3 is achieved by the Haber process: (Section 15.2)

$$N_2(g) + 3\,H_2(g) \longrightarrow 2\,NH_3(g) \qquad [22.35]$$

About 75% is used for fertilizer.

Hydrazine (N_2H_4) is another important hydride of nitrogen. The hydrazine molecule contains an N—N single bond (**Figure 22.22**). It can be prepared by the reaction of ammonia with hypochlorite ion (OCl^-) in aqueous solution:

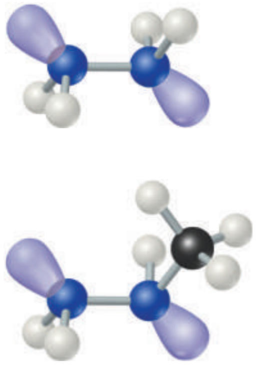
$$2\,NH_3(aq) + OCl^-(aq) \longrightarrow N_2H_4(aq) + Cl^-(aq) + H_2O(l) \qquad [22.36]$$

The reaction involves several intermediates, including chloramine (NH_2Cl). The poisonous NH_2Cl bubbles out of solution when household ammonia and chlorine bleach (which contains OCl^-) are mixed. This reaction is one reason for the frequently cited warning not to mix bleach and household ammonia.

Pure hydrazine is a strong and versatile reducing agent. The major use of hydrazine and compounds related to it, such as methylhydrazine (Figure 22.22), is as rocket fuel.

Go Figure

Is the N—N bond length in these molecules shorter or longer than the N—N bond length in N_2?



▲ **Figure 22.22** **Hydrazine (top, N_2H_4) and methylhydrazine (bottom, CH_3NHNH_2).** The purple lobes represent the orbitals where the lone pairs of electrons reside.

Sample Exercise 22.5
Writing a Balanced Equation

Hydroxylamine (NH_2OH) reduces copper(II) to the free metal in acid solutions. Write a balanced equation for the reaction, assuming that N_2 is the oxidation product.

SOLUTION

Analyze We are asked to write a balanced oxidation–reduction equation in which NH_2OH is converted to N_2 and Cu^{2+} is converted to Cu.

Plan Because this is a redox reaction, the equation can be balanced by the method of half-reactions discussed in Section 20.2. Thus, we begin with two half-reactions, one involving the NH_2OH and N_2 and the other involving Cu^{2+} and Cu.

Continued

Solve

The unbalanced and incomplete half-reactions are

$$Cu^{2+}(aq) \longrightarrow Cu(s)$$

$$NH_2OH(aq) \longrightarrow N_2(g)$$

Balancing these equations as described in Section 20.2 gives

$$Cu^{2+}(aq) + 2\,e^- \longrightarrow Cu(s)$$

$$2\,NH_2OH(aq) \longrightarrow N_2(g) + 2\,H_2O(l) + 2\,H^+(aq) + 2\,e^-$$

Adding these half-reactions gives the balanced equation:

$$Cu^{2+}(aq) + 2\,NH_2OH(aq) \longrightarrow Cu(s) + N_2(g) + 2\,H_2O(l) + 2\,H^+(aq)$$

Practice Exercise

Methylhydrazine, $N_2H_3CH_3(l)$, was used with the oxidizer dinitrogen tetroxide, $N_2O_4(l)$, to power the steering rockets of the Space Shuttle orbiter. The reaction of these two substances produces N_2, CO_2, and H_2O. Write a balanced equation for this reaction.

Oxides and Oxyacids of Nitrogen

Nitrogen forms three common oxides: N_2O (nitrous oxide), NO (nitric oxide), and NO_2 (nitrogen dioxide). It also forms two unstable oxides that we will not discuss: N_2O_3 (dinitrogen trioxide) and N_2O_5 (dinitrogen pentoxide).

Nitrous oxide (N_2O) is also known as laughing gas because a person becomes giddy after inhaling a small amount. This colorless gas was the first substance used as a general anesthetic. It is used as the compressed gas propellant in several aerosols and foams, such as in whipped cream.

Nitric oxide (NO) is also a colorless gas but, unlike N_2O, it is slightly toxic. It can be prepared in the laboratory by reduction of dilute nitric acid, using copper or iron as a reducing agent:

$$3\,Cu(s) + 2\,NO_3^-(aq) + 8\,H^+(aq) \longrightarrow 3\,Cu^{2+}(aq) + 2\,NO(g) + 4\,H_2O(l) \qquad [22.37]$$

Nitric oxide is also produced by direct reaction of N_2 and O_2 at high temperatures. This reaction is a significant source of nitrogen oxide air pollutants. (Section 18.2) The direct combination of N_2 and O_2 is not used for commercial production of NO, however, because the yield is low, the equilibrium constant K_p at 2400 K being only 0.05. [See the "Chemistry and Sustainability" box on "Controlling Nitric Oxide Emissions."[(Section 15.7)]

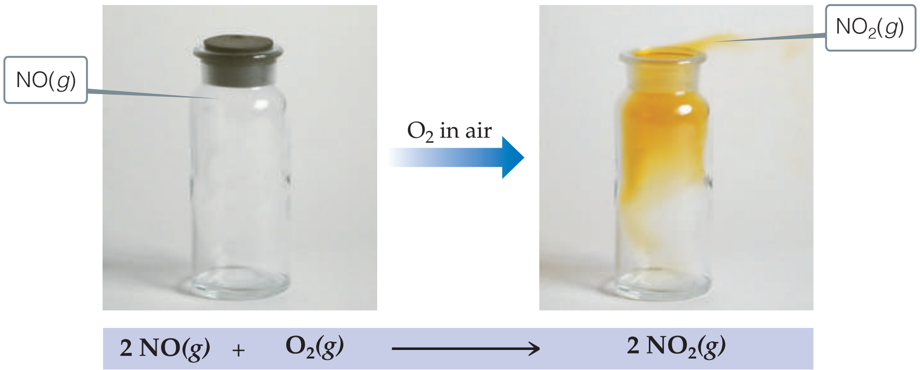
The commercial route to NO (and hence to other oxygen-containing compounds of nitrogen) is via the catalytic oxidation of NH_3:

$$4\,NH_3(g) + 5\,O_2(g) \xrightarrow[850\,°C]{\text{Pt catalyst}} 4\,NO(g) + 6\,H_2O(g) \qquad [22.38]$$

This reaction is the first step in the **Ostwald process**, by which NH_3 is converted commercially into nitric acid (HNO_3).

When exposed to air, nitric oxide reacts readily with O_2 (**Figure 22.23**):

$$2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g) \qquad [22.39]$$



▲ **Figure 22.23** **Formation of $NO_2(g)$ as NO(g) combines with $O_2(g)$ in the air.**

When dissolved in water, NO_2 forms nitric acid:

$$3\,NO_2(g) + H_2O(l) \longrightarrow 2\,H^+(aq) + 2\,NO_3^-(aq) + NO(g) \qquad [22.40]$$

Nitrogen is both oxidized and reduced in this reaction, which means it disproportionates. The NO can be converted back into NO_2 by exposure to air (Equation 22.39) and thereafter dissolved in water to prepare more HNO_3.

NO is an important neurotransmitter in the human body. It causes the muscles that line blood vessels to relax, thus allowing an increased passage of blood (see the "Chemistry and Life" box on "Nitroglycerin, Nitric Oxide, and Heart Disease" at the end of this section).

Nitrogen dioxide (NO_2) is a yellow-brown gas (Figure 22.23). Like NO, it is a major constituent of smog. (Section 18.2) It is poisonous and has a choking odor. As discussed in Section 15.1, NO_2 and N_2O_4 exist in equilibrium:

$$2\,NO_2(g) \rightleftharpoons N_2O_4(g) \quad \Delta H^\circ = -58\text{ kJ} \qquad [22.41]$$

The two common oxyacids of nitrogen are nitric acid (HNO_3) and nitrous acid (HNO_2) (**Figure 22.24**). *Nitric acid* is a strong acid. It is also a powerful oxidizing agent, as indicated by the standard reduction potential in the reaction

$$NO_3^-(aq) + 4\,H^+(aq) + 3\,e^- \longrightarrow NO(g) + 2\,H_2O(l) \quad E^\circ = +0.96\text{ V} \qquad [22.42]$$

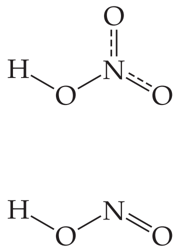
Concentrated nitric acid attacks and oxidizes most metals except Au, Pt, Rh, and Ir. Its largest use is in the manufacture of NH_4NO_3 for fertilizers. It is also used in the production of plastics, drugs, and explosives. Among the explosives made from nitric acid are nitroglycerin, trinitrotoluene (TNT), and nitrocellulose. The following reaction occurs when nitroglycerin explodes:

$$4\,C_3H_5N_3O_9(l) \longrightarrow 6\,N_2(g) + 12\,CO_2(g) + 10\,H_2O(g) + O_2(g) \qquad [22.43]$$

All the products of this reaction contain very strong bonds and are gases. As a result, the reaction is very exothermic, and the volume of the products is far larger than the volume occupied by the reactant. Thus, the expansion resulting from the heat generated by the reaction produces the explosion.

Go Figure

Which is the shortest NO bond in these two molecules?



▲ **Figure 22.24** **Structures of nitric acid (top) and nitrous acid (bottom).**

CHEMISTRY AND LIFE Nitroglycerin, Nitric Oxide, and Heart Disease

During the 1870s, an interesting observation was made in Alfred Nobel's dynamite factories. Workers who suffered from heart disease that caused chest pains when they exerted themselves found relief from the pains during the workweek. It quickly became apparent that nitroglycerin, present in the air of the factory, acted to enlarge blood vessels. Thus, this powerfully explosive chemical became a standard treatment for angina pectoris, the chest pains accompanying heart failure. It took more than 100 years to discover that nitroglycerin was converted in the vascular smooth muscle into NO, which is the chemical agent actually causing dilation of the blood vessels. In 1998, the Nobel Prize in Physiology or Medicine was awarded to Robert F. Furchgott, Louis J. Ignarro, and Ferid Murad for their discoveries of the detailed pathways by which NO acts in the cardiovascular system. It was a sensation that this simple, common air pollutant could exert important functions in mammals, including humans.

As useful as nitroglycerin is to this day in treating angina pectoris, it has a limitation in that prolonged administration results in development of tolerance, or desensitization, of the vascular muscle to further vasorelaxation by nitroglycerin. The bioactivation of nitroglycerin is the subject of active research in the hope that a means of circumventing desensitization can be found.

Self-Assessment Exercises

SAE 22.22 Select the correct formula for sodium nitride and indicate the oxidation state of nitrogen in this compound. (**a**) Na_3N, +1 (**b**) Na_3NO_3, −3 (**c**) $NaNO_3$, +5 (**d**) Na_3N, −3

SAE 22.23 Select the balanced equation for the reaction of nitric oxide and oxygen.

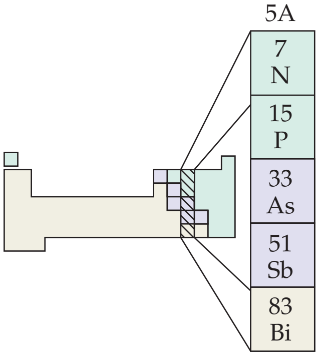
(**a**) $N_2(g) + O_2(g) \longrightarrow 2\,NO_2(g)$
(**b**) $2\,NO(g) + O_2(g) \longrightarrow 2\,NO_2(g)$
(**c**) $2\,N_2(g) + 5\,O_2(g) \longrightarrow 2\,N_2O_5(g)$
(**d**) $2\,N_2O(g) \longrightarrow 2\,N_2(g) + O_2(g)$

22.8 The Other Group 5A Elements: P, As, Sb, and Bi

Learning Objectives

When you are finished with Section 22.8, you should be able to:

- Compare and contrast the properties and reactivity of group 5A elements.
- Assign oxidation numbers to group 5A elements in their compounds.



Of the other group 5A elements—phosphorus, arsenic, antimony, and bismuth—phosphorus has a central role in several aspects of biochemistry and environmental chemistry.

The group 5A elements have the outer-shell electron configuration ns^2np^3, with n ranging from 2 to 6. A noble-gas configuration is achieved by adding three electrons to form the −3 oxidation state. Ionic compounds containing X^{3-} ions are not common, however. More commonly, the group 5A element acquires an octet of electrons via covalent bonding and oxidation numbers ranging from −3 to +5.

Because of its lower electronegativity, phosphorus is found more frequently in positive oxidation states than is nitrogen. Furthermore, compounds in which phosphorus has the +5 oxidation state are not as strongly oxidizing as the corresponding compounds of nitrogen. Compounds in which phosphorus has a −3 oxidation state are much stronger reducing agents than are the corresponding nitrogen compounds.

Some properties of the group 5A elements are listed in **Table 22.7**. The variation in properties among group 5A elements is more striking than that seen in groups 6A and 7A. Nitrogen at the one extreme exists as a gaseous diatomic molecule, making it nonmetallic. At the other extreme, bismuth is a silvery-pink solid, frequently iridescent due to an oxide layer, that has most of the characteristics of a metal.

The values listed for X—X single-bond enthalpies are not reliable because it is difficult to obtain such data from thermochemical experiments. However, there is no doubt about the general trend: a low value for the N—N single bond, an increase at phosphorus, and then a gradual decline to arsenic and antimony. From observations of the elements in the gas phase, it is possible to estimate the X≡X triple-bond enthalpies. Here, we see a trend that is different from that for the X—X single bond. Nitrogen forms a much stronger triple bond than the other elements, and there is a steady decline in the triple-bond enthalpy down through the group. These data help us to appreciate why nitrogen alone of the group 5A elements exists as a diatomic molecule in its stable state at 25 °C. All the other elements exist in structural forms with single bonds between the atoms.

Occurrence, Isolation, and Properties of Phosphorus

Phosphorus occurs mainly in the form of phosphate minerals. The principal source of phosphorus is phosphate rock, which contains phosphate principally as $Ca_3(PO_4)_2$. The element is produced commercially by the reduction of calcium phosphate with carbon in the presence of SiO_2:

$$2\,Ca_3(PO_4)_2(s) + 6\,SiO_2(s) + 10\,C(s) \xrightarrow{1500\,^{\circ}C} P_4(g) + 6\,CaSiO_3(l) + 10\,CO(g) \qquad [22.44]$$

The phosphorus produced in this fashion is the allotrope known as white phosphorus. This form distills from the reaction mixture as the reaction proceeds.

Phosphorus exists in several allotropic forms. White phosphorus consists of P_4 tetrahedra (**Figure 22.25**). The bond angles in this molecule, 60°, are unusually small, so there is much strain in the bonding, which is consistent with the high reactivity of white phosphorus. This allotrope bursts spontaneously into flames if exposed to air. When heated in the absence of air to about 400 °C, white phosphorus is converted to a more stable allotrope

TABLE 22.7 Properties of the Group 5A Elements

Property	N	P	As	Sb	Bi
Atomic radius (Å)	0.71	1.07	1.19	1.39	1.48

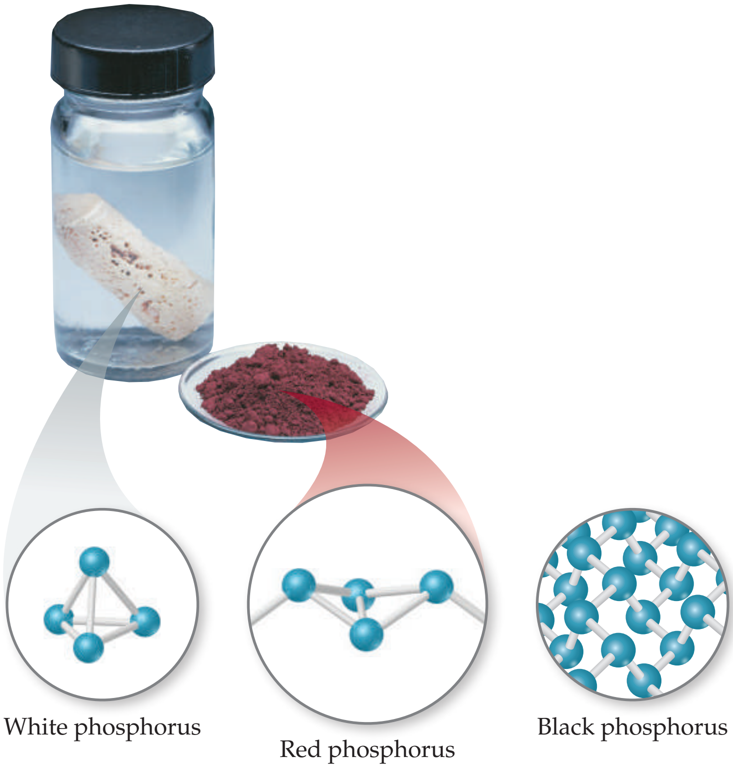
*Approximate values only.



▲ **Figure 22.25 White, red, and black phosphorus.** Despite the fact that they contain only phosphorus atoms, these forms of phosphorus differ greatly in reactivity. The white allotrope, which reacts violently with oxygen, must be stored under water so that it is not exposed to air. The much less reactive red and black forms do not need to be stored this way. Black phosphorus conducts electricity to some extent due to its structure.

known as red phosphorus, which does not ignite on contact with air. Red phosphorus is also considerably less poisonous than the white form. Another allotrope, black phosphorus, is an extended solid that is the thermodynamically stable form (by -39.3 kJ/mol) compared to white phosphorus. We denote elemental phosphorus as simply $P(s)$.

Phosphorus Halides

Phosphorus forms a wide range of compounds with the halogens, the most important of which are the trihalides and pentahalides. Phosphorus trichloride (PCl_3) is commercially the most significant of these compounds and is used to prepare a wide variety of products, including soaps, detergents, plastics, and insecticides.

Phosphorus chlorides, bromides, and iodides can be made by direct oxidation of elemental phosphorus with the elemental halogen. PCl_3, for example, which is a liquid at room temperature, is made by passing a stream of dry chlorine gas over white or red phosphorus:

$$2\,P(s) + 3\,Cl_2(g) \longrightarrow 2\,PCl_3(l) \qquad [22.45]$$

If excess chlorine gas is present, an equilibrium is established between PCl_3 and PCl_5.

$$PCl_3(l) + Cl_2(g) \rightleftharpoons PCl_5(s) \qquad [22.46]$$

The phosphorus halides react readily with water, and most fume in air because of reaction with water vapor. In the presence of excess water, the products are the corresponding phosphorus oxyacid and hydrogen halide:

$$PBr_3(l) + 3\,H_2O(l) \longrightarrow H_3PO_3(aq) + 3\,HBr(aq) \qquad [22.47]$$

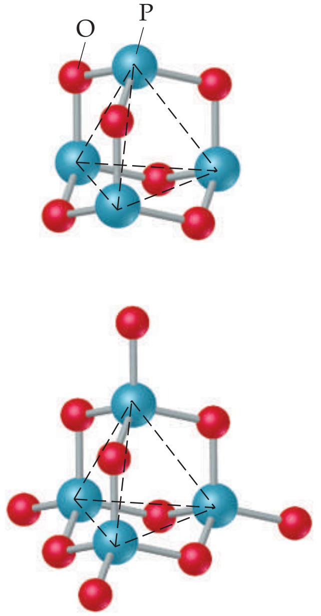
$$PCl_5(l) + 4\,H_2O(l) \longrightarrow H_3PO_4(aq) + 5\,HCl(aq) \qquad [22.48]$$

Oxy Compounds of Phosphorus

Probably the most significant phosphorus compounds are those in which the element is combined with oxygen. Phosphorus(III) oxide (P_4O_6) is obtained by allowing white

Go Figure

How do the electron domains about P in P_4O_6 differ from those about P in P_4O_{10}?

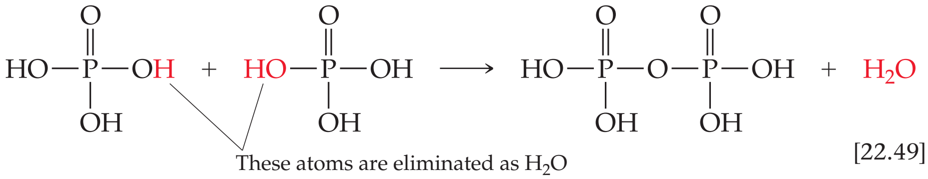


▲ **Figure 22.26 Structures of P_4O_6 (top) and P_4O_{10} (bottom).** The dashed lines outline the P_4 core in each molecule.

phosphorus to oxidize in a limited supply of oxygen. When oxidation takes place in the presence of excess oxygen, phosphorus(V) oxide (P_4O_{10}) forms. This compound is also readily formed by oxidation of P_4O_6. These two oxides represent the two most common oxidation states for phosphorus, +3 and +5. The structural relationship between P_4O_6 and P_4O_{10} is shown in **Figure 22.26**. Notice the resemblance these molecules have to the P_4 molecule (Figure 22.26); all three substances have a P_4 core.

Phosphorus(V) oxide is the anhydride of phosphoric acid (H_3PO_4), a weak triprotic acid. In fact, P_4O_{10} has a very high affinity for water and is consequently used as a drying agent. Phosphorus(III) oxide is the anhydride of phosphorous acid (H_3PO_3), a weak diprotic acid (**Figure 22.27**).*

One characteristic of phosphoric and phosphorous acids is their tendency to undergo *condensation reactions* when heated. (Section 12.6) For example, two H_3PO_4 molecules are joined by the elimination of one H_2O molecule to form $H_4P_2O_7$:



$$HO-\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle O}{\|}}{P}}-OH + HO-\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle O}{\|}}{P}}-OH \longrightarrow HO-\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle O}{\|}}{P}}-O-\underset{\underset{\displaystyle OH}{|}}{\overset{\overset{\displaystyle O}{\|}}{P}}-OH + H_2O \quad [22.49]$$

These atoms are eliminated as H_2O

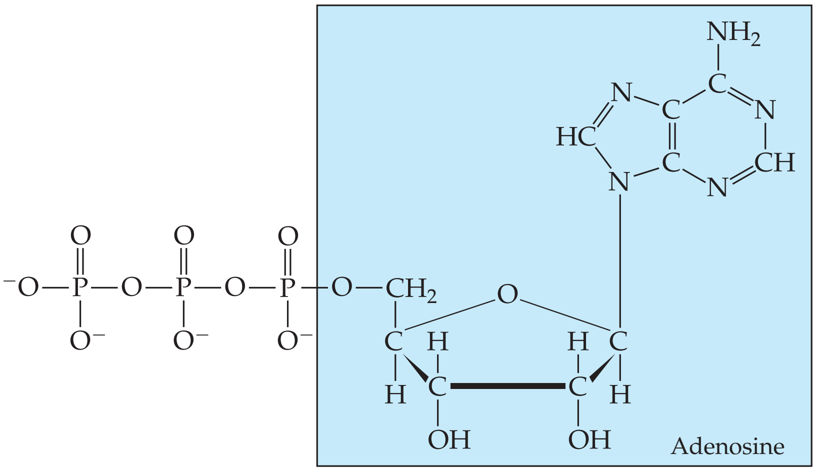
Phosphoric acid, its salts, and "polyphosphates" such as the product in Equation 22.49 find their most important uses in detergents and fertilizers. The phosphates in detergents are often in the form of sodium tripolyphosphate ($Na_5P_3O_{10}$). The phosphate ions "soften" water by binding their oxygen groups to the metal ions that contribute to the hardness of water. This keeps the metal ions from interfering with the action of the detergent. The phosphates also keep the pH above 7 and thus prevent the detergent molecules from becoming protonated.

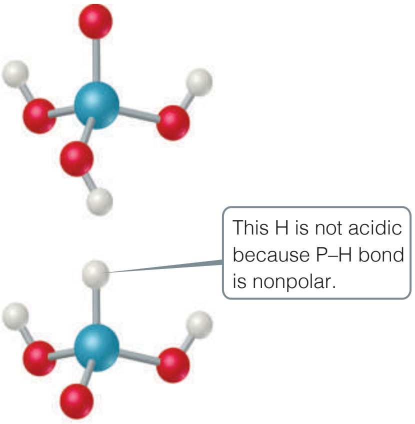
Most mined phosphate rock is converted to fertilizers. The $Ca_3(PO_4)_2$ in phosphate rock is insoluble ($K_{sp} = 2.0 \times 10^{-29}$). It is converted to a soluble form for use in fertilizers by treatment with sulfuric or phosphoric acid. The reaction with phosphoric acid yields $Ca(H_2PO_4)_2$:

$$Ca_3(PO_4)_2(s) + 4\,H_3PO_4(aq) \longrightarrow 3\,Ca^{2+}(aq) + 6\,H_2PO_4^{-}(aq) \qquad [22.50]$$

Although the solubility of $Ca(H_2PO_4)_2$ allows it to be assimilated by plants, it also allows it to be washed from the soil and into bodies of water, thereby contributing to water pollution. (Section 18.4)

Phosphorus compounds are important in biological systems. The element occurs in the phosphate groups in RNA and DNA, the molecules responsible for the control of protein biosynthesis and transmission of genetic information. It also occurs in adenosine triphosphate (ATP), which stores energy in biological cells and has the following structure:





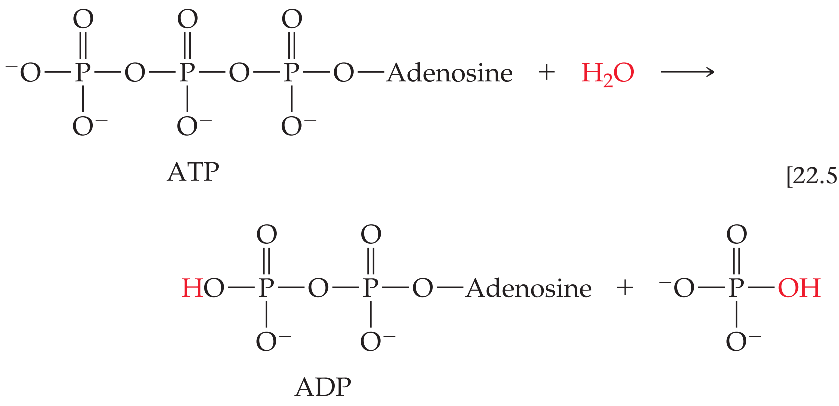
This H is not acidic because P–H bond is nonpolar.

▲ **Figure 22.27 Structures of H_3PO_4 (top) and H_3PO_3 (bottom).**

---

*Note that the element phosphorus (*FOS·for·us*) has a *-us* suffix, whereas the first word in the name phosphorous (*fos·FOR·us*) acid has an *-ous* suffix.

The P—O—P bond of the end phosphate group is broken by hydrolysis with water, forming adenosine diphosphate (ADP):



$$ {}^{-}\text{O}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{O}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{O}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{O}-\text{Adenosine} + H_2O \longrightarrow \quad [22.51] $$

$$ \text{HO}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{O}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{O}-\text{Adenosine} + {}^{-}\text{O}-\underset{\text{O}^-}{\overset{\text{O}}{\overset{\|}{\underset{|}{\text{P}}}}}-\text{OH} $$

This reaction releases 33 kJ of energy under standard conditions, but in the living cell, the Gibbs free energy change for the reaction is closer to -57 kJ/mol. The concentration of ATP inside a living cell is in the range of 1–10 m*M*, and a typical human metabolizes her or his body mass of ATP in one day! ATP is continually made from ADP and is continually converted back to ADP, releasing energy that can be harnessed by other cellular reactions.

Arsenic, Antimony, and Bismuth

The heavier members of group 5A are mostly known for their effects on human health. Arsenic in the form of As_2O_3, known as "white arsenic," was used for decades at a commercial rat poison and illegally as a way to poison people. The well-known Marsh test for arsenic, used from the 1840s through the 1970s in crime scene investigations, involves a redox reaction of samples containing white arsenic with sulfuric acid and zinc upon the application of heat:

$$ As_2O_3(s) + 6\,Zn(s) + 6\,H_2SO_4(aq) \longrightarrow 2\,AsH_3(g) + 6\,ZnSO_4(aq) + 3\,H_2O(l) \quad [22.52] $$

In the Marsh test apparatus, a glass or ceramic bowl was placed near the reaction site; the hot gaseous arsine, AsH_3, would decompose to elemental arsenic there, creating a characteristic silvery-black "mirror" film on the bowl. Antimony reacts similar to arsenic in the Marsh test, but can be distinguished from As upon reaction of the mirror film with sodium hypochlorite: the arsenic mirror will dissolve upon reaction with sodium hypochlorite, but the antimony mirror will remain.

Arsenic, antimony, and bismuth react quite similarly to phosphorus to make oxyanions, halide compounds, and others. The most well-known compound of bismuth is bismuth subsalicylate, the pink colloidal solution known as Pepto-Bismol® that is used to treat minor gastrointestinal illnesses (see the "Putting Concepts Together" feature at the end of Section 7.7).

CHEMISTRY AND LIFE **Arsenic in Drinking Water**

Arsenic, in the form of its oxides, has been known as a poison for centuries. The current Environmental Protection Agency (EPA) standard for arsenic in public water supplies is 10 ppb (equivalent to 10 μg/L). Most regions of the United States tend to have low to moderate (2–10 ppb) groundwater arsenic levels (**Figure 22.28**). The western region tends to have higher levels, coming mainly from natural geological sources in the area. Estimates, for example, indicate that 35% of water-supply wells in Arizona have arsenic concentrations above 10 ppb.

The problem of arsenic in drinking water in the United States is dwarfed by the problem in other parts of the world—especially in Bangladesh, where the problem is tragic. Historically, surface water sources in that country have been contaminated with microorganisms, causing significant health problems. During the 1970s, international agencies, headed by the United Nations Children's Fund (UNICEF), began investing millions of dollars of aid money in Bangladesh for wells to provide "clean" drinking water. Unfortunately, no one tested the well water for the presence of arsenic; the problem was not discovered until the 1980s. The result has been the biggest outbreak of mass poisoning in history. Up to half of the country's estimated 10 million wells have arsenic concentrations above 50 ppb.

In water, the most common forms of arsenic are the arsenate ion and its protonated hydrogen anions (AsO_4^{3-}, $HAsO_4^{2-}$, and

Continued

$H_2AsO_4^-$) and the arsenite ion and its protonated forms (AsO_3^{3-}, $HAsO_3^{2-}$, $H_2AsO_3^-$, and H_3AsO_3). These species are collectively referred to by the oxidation number of the arsenic as arsenic(V) and arsenic(III), respectively. Arsenic(V) is more prevalent in oxygen-rich (aerobic) surface waters, whereas arsenic(III) is more likely to occur in oxygen-poor (anaerobic) groundwaters.

One of the challenges in determining the health effects of arsenic in drinking waters is the different chemistry of arsenic(V) and arsenic(III), as well as the different concentrations required for physiological responses in different individuals. In Bangladesh, skin lesions were the first sign of the arsenic problem. Statistical studies correlating arsenic levels with the occurrence of disease indicate a lung and bladder cancer risk arising from even low levels of arsenic.

The current technologies for removing arsenic perform most effectively when treating arsenic in the form of arsenic(V), so water treatment strategies require preoxidation of the drinking water. Once in the form of arsenic(V), there are a number of possible removal strategies. For example, Fe^{3+} can be added to precipitate $FeAsO_4$, which is then removed by filtration.

22.9 | Carbon

Learning Objectives

When you have finished Section 22.9, you should be able to:

- Give the name of a carbon-containing compound, determine its chemical formula, and vice versa.
- Write balanced chemical equations for reactions involving carbon.

Carbon constitutes only 0.027% of Earth's crust. Although some carbon occurs in elemental form as graphite and diamond, most is found in combined form. Over half occurs in carbonate compounds. Carbon is also found in coal, petroleum, and natural gas. The importance of the element stems in large part from its occurrence in all living organisms: Life as we know it is based on carbon compounds.

Elemental Forms of Carbon

We have seen that carbon exists in several allotropic crystalline forms: graphite, diamond, fullerenes, carbon nanotubes, and graphene. Fullerenes, nanotubes, and graphene are discussed in Chapter 12; here we focus on graphite and diamond.

Graphite is a soft, black, slippery solid that has a metallic luster and conducts electricity. It consists of parallel sheets of sp^2-hybridized carbon atoms held together by dispersion forces [see Figure 12.28(b)]. (Section 12.5) *Diamond* is a clear, hard solid in which the carbon atoms form an sp^3-hybridized covalent network [see Figure 12.28(a)]. (Section 12.5) Diamond is denser than graphite ($d = 2.25\ \text{g/cm}^3$ for graphite; $d = 3.51\ \text{g/cm}^3$ for diamond). At approximately 100,000 atm at 3000 °C, graphite converts to diamond. In fact, almost any carbon-containing substance, if put under sufficiently high pressure, forms diamonds; scientists at General Electric in the 1950s used peanut butter to make diamonds. About 3×10^4 kg of industrial-grade diamonds are synthesized each year, mainly for use in cutting, grinding, and polishing tools.

Graphite has a well-defined crystalline structure, but it also exists in two common amorphous forms: **carbon black** and **charcoal**. Carbon black is formed when hydrocarbons are heated in a very limited supply of oxygen, such as in this methane reaction:

$$CH_4(g) + O_2(g) \longrightarrow C(s) + 2\,H_2O(g) \qquad [22.53]$$

Carbon black is used as a pigment in black inks; large amounts are also used in making automobile tires.

Charcoal is formed when wood is heated strongly in the absence of air. Charcoal has an open structure, giving it an enormous surface area per unit mass. "Activated charcoal," a pulverized form of charcoal whose surface is cleaned by heating with steam, is widely used to adsorb molecules. It is used in filters to remove offensive odors from air and colored or bad-tasting impurities from water.

Oxides of Carbon

Carbon forms two principal oxides: carbon monoxide (CO) and carbon dioxide (CO_2). *Carbon monoxide* is formed when carbon or hydrocarbons are burned in a limited supply of oxygen:

$$2\,C(s) + O_2(g) \longrightarrow 2\,CO(g) \qquad [22.54]$$

CO is a colorless, odorless, tasteless gas that is toxic because it binds to hemoglobin in the blood and thus interferes with oxygen transport. Low-level poisoning results in headaches and drowsiness; high-level poisoning can cause death.

Carbon monoxide is unusual in that it has a nonbonding pair of electrons on carbon: $:C{\equiv}O:$. It is isoelectronic with N_2, so you might expect CO to be equally unreactive. Moreover, both substances have high bond energies (1072 kJ/mol for $C{\equiv}O$ and 941 kJ/mol for $N{\equiv}N$). Because of the lower nuclear charge on carbon (compared with either N or O), however, the carbon nonbonding pair is not held as strongly as that on N or O. Consequently, CO is better able to function as a Lewis base than is N_2; for example, CO can coordinate its nonbonding pair to the iron of hemoglobin, displacing O_2, but N_2 cannot.

A CLOSER LOOK Carbon Fibers and Composites

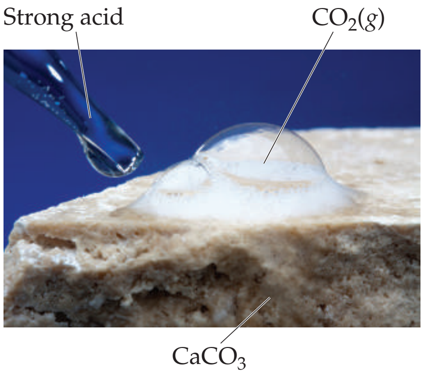
The properties of graphite are anisotropic; that is, they differ in different directions through the solid. Along the carbon planes, graphite possesses great strength because of the number and strength of the carbon–carbon bonds in this direction. The bonds between planes are relatively weak, however, making graphite weak in that direction.

Fibers of graphite can be prepared in which the carbon planes are aligned to varying extents parallel to the fiber axis. These fibers are lightweight (density of about 2 g/cm^3) and chemically quite unreactive. The oriented fibers are made by first slowly pyrolyzing (decomposing by action of heat) organic fibers at about 150 to 300 °C. These fibers are then heated to about 2500 °C to graphitize them (convert amorphous carbon to graphite). Stretching the fiber during pyrolysis helps orient the graphite planes parallel to the fiber axis. More amorphous carbon fibers are formed by pyrolysis of organic fibers at lower temperatures (400 to 1200 °C). These amorphous materials, commonly called *carbon fibers*, are the type most often used in commercial materials.

Composite materials that take advantage of the strength, stability, and low density of carbon fibers are widely used. Composites are combinations of two or more materials. These materials are present as separate phases and are combined to form structures that take advantage of certain desirable properties of each component. In carbon composites, the graphite fibers are often woven into a fabric that is embedded in a matrix that binds them into a solid structure. The fibers transmit loads evenly throughout the matrix. The finished composite is thus stronger than any one of its components.

Carbon composite materials are used widely in a number of applications, including high-performance graphite sports equipment such as tennis racquets, golf clubs, and bicycle wheels (**Figure 22.29**). Heat-resistant composites are required for many aerospace applications, where carbon composites now find wide use.

▲ **Figure 22.29 Carbon composites in commercial products.**



▲ **Figure 22.30** **CO_2 formation from the reaction between an acid and calcium carbonate in rock.**

Carbon monoxide has several commercial uses. Because it burns readily, forming CO_2, it is employed as a fuel:

$$2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g) \qquad \Delta H^\circ = -566\text{ kJ} \qquad [22.55]$$

Carbon monoxide is an important reducing agent, widely used in metallurgical operations to reduce metal oxides, such as the iron oxides:

$$Fe_3O_4(s) + 4\,CO(g) \longrightarrow 3\,Fe(s) + 4\,CO_2(g) \qquad [22.56]$$

Carbon dioxide is produced when carbon-containing substances are burned in excess oxygen, such as in this reaction involving ethanol:

$$C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(g) \qquad [22.57]$$

It is also produced when many carbonates are heated:

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g) \qquad [22.58]$$

In the laboratory, CO_2 can be produced by the action of acids on carbonates (**Figure 22.30**):

$$CO_3^{2-}(aq) + 2\,H^+(aq) \longrightarrow CO_2(g) + H_2O(l) \qquad [22.59]$$

Carbon dioxide is a colorless, odorless gas. It is a minor component of Earth's atmosphere but a major contributor to the greenhouse effect. (Section 18.2) Although it is not toxic, high concentrations of CO_2 increase respiration rate and can cause suffocation. It is readily liquefied by compression. When cooled at atmospheric pressure, however, CO_2 forms a solid rather than liquefying. The solid sublimes at atmospheric pressure at −78 °C. This property makes solid CO_2, known as *dry ice*, valuable as a refrigerant. About half of the CO_2 consumed annually is used for refrigeration. The other major use of CO_2 is in the production of carbonated beverages. Large quantities are also used to manufacture *washing soda* ($Na_2CO_3 \cdot 10\,H_2O$), used to precipitate metal ions that interfere with the cleansing action of soap, and *baking soda* ($NaHCO_3$). Baking soda is so named because the following reaction occurs during baking:

$$NaHCO_3(s) + H^+(aq) \longrightarrow Na^+(aq) + CO_2(g) + H_2O(l) \qquad [22.60]$$

The $H^+(aq)$ is provided by vinegar, sour milk, or the hydrolysis of certain salts. The bubbles of CO_2 that form are trapped in the baking dough, causing it to rise.

Carbonic Acid and Carbonates

Carbon dioxide is moderately soluble in H_2O at atmospheric pressure. The resulting solution is moderately acidic because of the formation of carbonic acid (H_2CO_3):

$$CO_2(aq) + H_2O(l) \rightleftharpoons H_2CO_3(aq) \qquad [22.61]$$

Carbonic acid is a weak diprotic acid. Its acidic character causes carbonated beverages to have a sharp, slightly acidic taste.

Although carbonic acid is unstable and cannot be isolated, hydrogen carbonates (also called bicarbonates) and carbonates can be obtained by neutralizing carbonic acid solutions. Partial neutralization produces HCO_3^-, and complete neutralization gives CO_3^{2-}. The HCO_3^- ion could in theory function either as an acid or as a base, but it is a stronger base than acid ($K_b = 2.3 \times 10^{-8}$; $K_a = 5.6 \times 10^{-11}$). The carbonate ion is much more strongly basic than bicarbonate ($K_b = 1.8 \times 10^{-4}$).

The principal carbonate minerals are calcite ($CaCO_3$), magnesite ($MgCO_3$), dolomite [$MgCa(CO_3)_2$], and siderite ($FeCO_3$). Calcite is the principal mineral in limestone and the main constituent of marble, chalk, pearls, coral reefs, and the shells of marine animals such as clams and oysters. Although $CaCO_3$ has low solubility in pure water, it dissolves readily in acidic solutions with evolution of CO_2:

$$CaCO_3(s) + 2\,H^+(aq) \rightleftharpoons Ca^{2+}(aq) + H_2O(l) + CO_2(g) \qquad [22.62]$$

Because water containing CO_2 is slightly acidic (Equation 22.61), $CaCO_3$ dissolves slowly in this medium:

$$\text{CaCO}_3(s) + \text{H}_2\text{O}(l) + \text{CO}_2(g) \longrightarrow \text{Ca}^{2+}(aq) + 2\,\text{HCO}_3^-(aq) \qquad [22.63]$$

This reaction occurs when surface waters move underground through limestone deposits. It is the principal way Ca^{2+} enters groundwater, producing *hard water*, (water with a high mineral content, containing especially Ca^{2+} and Mg^{2+} ions). If the limestone deposit is deep enough underground, dissolution of the limestone produces a cave.

One of the most important reactions of $CaCO_3$ is its decomposition into CaO and CO_2 at elevated temperatures (Equation 22.58). Because calcium oxide, known as lime or quicklime, reacts with water to form $Ca(OH)_2$, it is an important commercial base. It is also important in making mortar, the mixture of sand, water, and CaO used to bind bricks, blocks, or rocks together. Calcium oxide reacts with water and CO_2 to form $CaCO_3$, which binds the sand in the mortar:

$$\text{CaO}(s) + \text{H}_2\text{O}(l) \longrightarrow \text{Ca}^{2+}(aq) + 2\,\text{OH}^-(aq) \qquad [22.64]$$

$$\text{Ca}^{2+}(aq) + 2\,\text{OH}^-(aq) + \text{CO}_2(aq) \longrightarrow \text{CaCO}_3(s) + \text{H}_2\text{O}(l) \qquad [22.65]$$

Carbides

The binary compounds of carbon with metals, metalloids, and certain nonmetals are called **carbides**. The more active metals form *ionic carbides*, and the most common of these contain the *acetylide* ion (C_2^{2-}). This ion is isoelectronic with N_2, and its Lewis structure, $[:\text{C}\equiv\text{C}:]^{2-}$, has a carbon–carbon triple bond. The most important ionic carbide is calcium carbide (CaC_2), produced by the reduction of CaO with carbon at high temperature:

$$2\,\text{CaO}(s) + 5\,\text{C}(s) \longrightarrow 2\,\text{CaC}_2(s) + \text{CO}_2(g) \qquad [22.66]$$

The carbide ion is a very strong base that reacts with water to form acetylene ($\text{H—C}\equiv\text{C—H}$):

$$\text{CaC}_2(s) + 2\,\text{H}_2\text{O}(l) \longrightarrow \text{Ca(OH)}_2(aq) + \text{C}_2\text{H}_2(g) \qquad [22.67]$$

Calcium carbide is therefore a convenient solid source of acetylene, which is used in welding (Figure 22.11).

Interstitial carbides are formed by many transition metals. The carbon atoms occupy open spaces (interstices) between the metal atoms in a manner analogous to the interstitial hydrides. (Section 22.2) This process generally makes the metal harder. Tungsten carbide (WC), for example, is very hard and very heat-resistant and, thus, used to make cutting tools.

Covalent carbides are formed by boron and silicon. Silicon carbide (SiC), known as Carborundum®, is used as an abrasive and in cutting tools. Almost as hard as diamond, SiC has a diamond-like structure with alternating Si and C atoms.

(**a**) Only one statement of i, ii, and iii is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

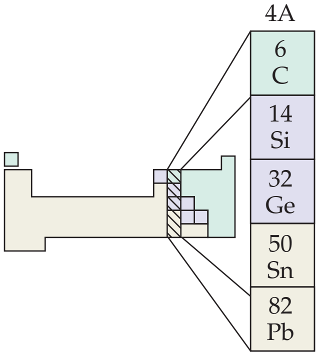
22.10 | The Other Group 4A Elements: Si, Ge, Sn, and Pb

Learning Objectives

When you finish Section 22.10, you should be able to:

- Determine the oxidation states of group 4A elements in compounds.
- Compare and contrast the properties and reactivity of compounds containing heavier group 4A elements to compounds containing carbon.
- Use the formula of a silicate mineral to determine its general structure.

The trend from nonmetallic to metallic character as we go down a family is strikingly evident in group 4A. Carbon is a nonmetal; silicon and germanium are metalloids; tin and lead are metals. In this section, we consider a few general characteristics of group 4A and then look more thoroughly at silicon.



General Characteristics of the Group 4A Elements

The group 4A elements possess the outer-shell electron configuration ns^2np^2, with n ranging from 2 to 6. The electronegativities of the elements are generally low (**Table 22.8**); carbides that formally contain C^{4-} ions are observed only in the case of a few compounds of carbon with very active metals. Formation of 4+ ions by electron loss is not observed for any of these elements; the ionization energies are too high. The +4 oxidation state is common, however, and is found in the vast majority of the compounds of the group 4A elements. The +2 oxidation state is found in the chemistry of germanium, tin, and lead, however, and it is the principal oxidation state for lead. Carbon usually forms a maximum of four bonds. The other members of the family are able to form more than four bonds. (Section 8.7)

Table 22.8 shows that the strength of a bond between two atoms of a given element decreases as we go down group 4A. Carbon–carbon bonds are quite strong. Carbon, therefore, has a striking ability to form compounds in which carbon atoms are bonded to one another in extended chains and rings, which accounts for the large number of organic compounds that exist. Other elements can form chains and rings, but these bonds are far less important in the chemistries of these other elements. The Si—Si bond strength (226 kJ/mol), for example, is much lower than the Si—O bond strength (386 kJ/mol). As a result, the chemistry of silicon is dominated by the formation of Si—O bonds, and Si—Si bonds play a minor role.

Go Figure

▲ **Figure 22.31 Zone-refining apparatus for the production of ultrapure silicon.**

Occurrence and Preparation of Silicon

Silicon is the second most abundant element, after oxygen, in Earth's crust. It occurs in SiO_2 (the empirical formula for quartz and sand) and in an enormous variety of silicate minerals. The element is obtained by the reduction of molten silicon dioxide with carbon at high temperature:

$$SiO_2(l) + 2\,C(s) \longrightarrow Si(l) + 2\,CO(g) \qquad [22.68]$$

Elemental silicon has a diamond-like structure. Crystalline silicon is a gray metallic-looking solid that melts at 1410 °C. The element is a semiconductor, as we saw in Chapters 7 and 12, and is used to make solar cells and transistors for computer chips. To be used as a semiconductor, it must be extremely pure, possessing less than $10^{-7}\%$ (1 ppb) impurities. One method of purification is to treat the element with Cl_2 to form $SiCl_4$, a volatile liquid that is purified by fractional distillation and then converted back to elemental silicon by reduction with H_2:

$$SiCl_4(g) + 2\,H_2(g) \longrightarrow Si(s) + 4\,HCl(g) \qquad [22.69]$$

The process known as *zone refining* can further purify the element (**Figure 22.31**). As a heated coil is passed slowly along a silicon rod, a narrow band of the element is melted. As

the molten section is swept slowly along the length of the rod, the impurities concentrate in this section, following it to the end of the rod. The purified top portion of the rod crystallizes as 99.999999999% pure silicon.

Silicates

Silicon dioxide and other compounds that contain silicon and oxygen make up over 90% of Earth's crust. In **silicates**, a silicon atom is surrounded by four oxygens, and silicon is found in its most common oxidation state, +4. The orthosilicate ion, SiO_4^{4-}, is found in very few silicate minerals, but we can view it as the "building block" for many mineral structures. As Figure 22.32 shows, adjacent tetrahedra can be linked by a common oxygen atom. Two tetrahedra joined in this way, called the *disilicate* ion, contain two Si atoms and seven O atoms. Silicon and oxygen are in the +4 and −2 oxidation states, respectively, in all silicates, so the overall charge of any silicate ion must be consistent with these oxidation states. For example, the charge on Si_2O_7 is $(2)(+4) + (7)(-2) = -6$; it is the $Si_2O_7^{6-}$ ion.

In most silicate minerals, silicate tetrahedra are linked together to form chains, sheets, or three-dimensional structures. We can connect two vertices of each tetrahedron to two other tetrahedra, for example, leading to an infinite chain with an $\cdots$ O—Si—O—Si $\cdots$ backbone as shown in Figure 22.32(b). Notice that each silicon in this structure has two unshared (terminal) oxygens and two shared (bridging) oxygens. The stoichiometry is then $2(1) + 2(1/2) = 3$ oxygens per silicon. Thus, the formula unit for this chain is SiO_3^{2-}. The mineral *enstatite* ($MgSiO_3$) has this kind of structure, consisting of rows of single-strand silicate chains with Mg^{2+} ions between the strands to balance charge.

In Figure 22.32(c), each silicate tetrahedron is linked to three others, forming an infinite sheet structure. Each silicon in this structure has one unshared oxygen and three shared oxygens. The stoichiometry is then $1(1) + 3(½) = 2½$ oxygens per silicon. The simplest formula of this sheet is $Si_2O_5^{2-}$. The mineral *talc*, also known as talcum powder, has the formula $Mg_3(Si_2O_5)_2(OH)_2$ and is based on this sheet structure. The Mg^{2+} and OH^- ions lie between the silicate sheets. The slippery feel of talcum powder is due to the silicate sheets sliding relative to one another.

Asbestos is a general term applied to a group of fibrous silicate minerals. The structure of these minerals is either chains of silicate tetrahedra or sheets formed into rolls. The result is that the minerals have a fibrous character (Figure 22.33). Asbestos minerals were once widely used as thermal insulation, especially in high-temperature applications, because of the great chemical stability of the silicate structure. In addition, the fibers can be woven into asbestos cloth, which was once used for fireproof curtains and

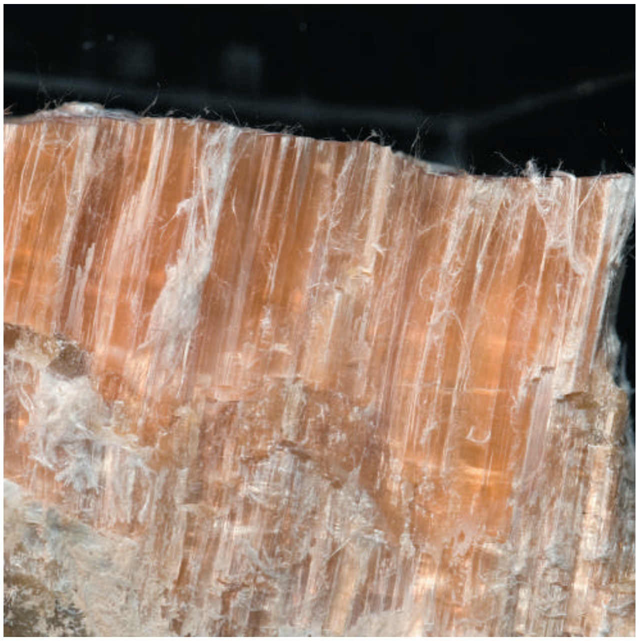

Figure 22.33 Serpentine asbestos.

other applications. However, the fibrous structure of asbestos minerals poses a health risk because the fibers readily penetrate soft tissues, such as the lungs, where they can cause diseases, including cancer. The use of asbestos as a common building material has therefore been discontinued.

When all four vertices of each SiO_4 tetrahedron are linked to other tetrahedra, the structure extends in three dimensions. This linking of the tetrahedra forms quartz (SiO_2). Because the structure is locked together in a three-dimensional array much like diamond (Section 12.5), quartz is harder than strand- or sheet-type silicates.

Sample Exercise 22.6

Determining an Empirical Formula

The mineral *chrysotile* is a noncarcinogenic asbestos mineral that is based on the sheet structure shown in Figure 22.32(c). In addition to silicate tetrahedra, the mineral contains Mg^{2+} and OH^- ions. Analysis of the mineral shows that there are 1.5 Mg atoms per Si atom. What is the empirical formula for chrysotile?

SOLUTION

Analyze A mineral is described that has a sheet silicate structure with Mg^{2+} and OH^- ions to balance charge and 1.5 Mg for each 1 Si. We are asked to write the empirical formula for the mineral.

Plan As shown in Figure 22.32(c), the silicate sheet structure has the simplest formula $Si_2O_5^{2-}$. We first add Mg^{2+} to give the proper Mg:Si ratio. We then add OH^- ions to obtain a neutral compound.

Solve
The observation that the Mg:Si ratio equals 1.5 is consistent with three Mg^{2+} ions per $Si_2O_5^{2-}$ unit. The addition of three Mg^{2+} ions would make $Mg_3(Si_2O_5)^{4+}$. In order to achieve charge balance in the mineral, there must be four OH^- per $Si_2O_5^{2-}$. Thus, the formula of chrysotile is $Mg_3(Si_2O_5)(OH)_4$. Because this is not reducible to a simpler formula, this is the empirical formula.

Practice Exercise

The cyclosilicate ion consists of three silicate tetrahedra linked together in a ring. The ion contains three Si atoms and nine O atoms. What is the overall charge on the ion?

Glass

Quartz melts at approximately 1600 °C, forming a tacky liquid. In the course of melting, many silicon–oxygen bonds are broken. When the liquid cools rapidly, silicon–oxygen bonds are re-formed before the atoms are able to arrange themselves in a regular fashion. An amorphous solid, known as quartz glass or silica glass, results. Many substances can be added to SiO_2 to cause it to melt at a lower temperature. The common **glass** used in windows and bottles, known as soda-lime glass, contains CaO and Na_2O in addition to

SiO_2 from sand. The CaO and Na_2O are produced by heating two inexpensive chemicals, limestone ($CaCO_3$) and soda ash (Na_2CO_3), which decompose at high temperatures:

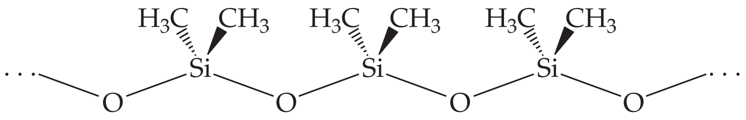
$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g) \qquad [22.70]$$

$$Na_2CO_3(s) \longrightarrow Na_2O(s) + CO_2(g) \qquad [22.71]$$

Other substances can be added to soda-lime glass to produce color or to change the properties of the glass in various ways. The addition of CoO, for example, produces the deep blue color of "cobalt glass." Replacing Na_2O with K_2O results in a harder glass that has a higher melting point. Replacing CaO with PbO results in a denser "lead crystal" glass with a higher refractive index. Lead crystal is used for decorative glassware; the higher refractive index gives this glass a particularly sparkling appearance. Addition of nonmetal oxides, such as B_2O_3 and P_4O_{10}, which form network structures related to the silicates, also changes the properties of the glass. Adding B_2O_3 creates a "borosilicate" glass with a higher melting point and a greater ability to withstand temperature changes. Such glasses, sold commercially under trade names such as Pyrex® and Kimax®, are used where resistance to thermal shock is important, such as in laboratory glassware or coffeemakers.

Silicones

Silicones consist of O—Si—O chains in which the two remaining bonding positions on each silicon are occupied by organic groups such as CH_3:



Depending on chain length and degree of cross-linking, silicones can be either oils or rubber-like materials. Silicones are nontoxic and have good stability toward heat, light, oxygen, and water. They are used commercially in a wide variety of products, including lubricants, car polishes, sealants, and gaskets. They are also used for waterproofing fabrics. When applied to a fabric, the oxygen atoms form hydrogen bonds with the molecules on the surface of the fabric. The hydrophobic (water-repelling) organic groups of the silicone are then left pointing away from the surface as a barrier.

Self-Assessment Exercises

SAE 22.30 What is the chemical formula for lead(II) chloride, and what is the oxidation state of lead in this compound? (**a**) $PbCl_2$, +2 (**b**) $PbCl_2$, −2 (**c**) PbCl, +1 (**d**) Pb_2Cl, +0.5

SAE 22.31 Which group 4A element has the highest first ionization energy? (**a**) germanium (**b**) tin (**c**) lead (**d**) silicon

SAE 22.32 In which of the following silicate minerals would you expect to find chains of corner-connected SiO_4 tetrahedra? (**a**) Na_2SiO_3 (**b**) Na_4SiO_4 (**c**) $Na_6Si_2O_7$ (**d**) $Mg_3Si_2O_5(OH)_4$

22.11 | Boron

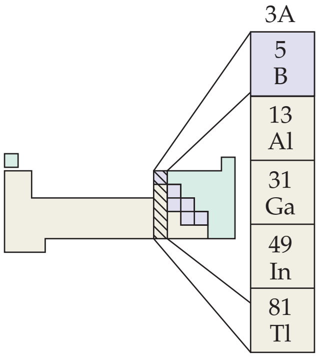
Boron is the only group 3A element that can be considered nonmetallic; thus, it is our final element in this chapter. The element has an extended network structure with a melting point (2300 °C) that is intermediate between the melting points of carbon (3550 °C) and silicon (1410 °C). The electron configuration of boron is $[He]2s^22p^1$.

In the family of compounds called **boranes**, the molecules contain only boron and hydrogen. Because B is less electronegative than H, the B—H bond in these compounds is polarized, with H having the higher electron density. The simplest borane is BH_3. This molecule contains only six valence electrons and is therefore an exception to the octet rule. As a result, BH_3 reacts with itself to form *diborane* (B_2H_6). This reaction can be

Learning Objectives

When you finish Section 22.11, you should be able to:

- Predict bonding in boranes.
- Write balanced chemical equations for reactions involving boron-containing compounds.



viewed as a Lewis acid–base reaction in which one B—H bonding pair of electrons in each BH_3 molecule is donated to the other. As a result, diborane is an unusual molecule in which hydrogen atoms form a bridge between two B atoms (**Figure 22.34**). Such hydrogens are called *bridging hydrogens*.

Sharing hydrogen atoms between the two boron atoms compensates somewhat for the deficiency in valence electrons around each boron. Nevertheless, diborane is an extremely reactive molecule, spontaneously flammable in air in a highly exothermic reaction:

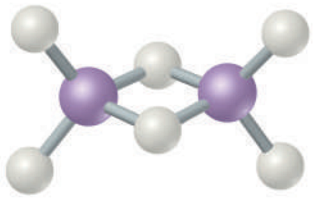
$$B_2H_6(g) + 3\,O_2(g) \longrightarrow B_2O_3(s) + 3\,H_2O(g) \qquad \Delta H^\circ = -2030\text{ kJ} \qquad [22.72]$$

Boron and hydrogen form a series of anions called *borane anions*. Salts of the borohydride ion (BH_4^-) are widely used as reducing agents. For example, sodium borohydride ($NaBH_4$) is a commonly used reducing agent for certain organic compounds.

The only important oxide of boron is boric oxide (B_2O_3). This substance is the anhydride of boric acid, which we may write as H_3BO_3 or $B(OH)_3$. Boric acid is so weak an acid ($K_a = 5.8 \times 10^{-10}$) that solutions of H_3BO_3 are used as an eyewash. Upon heating, boric acid loses water by a condensation reaction similar to that described for phosphorus in Section 22.8:

$$4\,H_3BO_3(s) \longrightarrow H_2B_4O_7(s) + 5\,H_2O(g) \qquad [22.73]$$

The diprotic acid $H_2B_4O_7$ is tetraboric acid. The hydrated sodium salt $Na_2B_4O_7 \cdot 10\,H_2O$, called borax, occurs in dry lake deposits in California and can also be prepared from other borate minerals. Solutions of borax are alkaline, and the substance is used in various laundry and cleaning products.



▲ **Figure 22.34** **The structure of diborane (B_2H_6).**

Self-Assessment Exercises

SAE 22.33 In a molecule of diborane, B_2H_6, there are ______ valence electrons and ______ B—H bonds. (**a**) 16, 8 (**b**) 12, 8 (**c**) 12, 6 (**d**) 14, 7

SAE 22.34 Which of the following is the balanced equation that describes the reaction between diborane and oxygen?

(**a**) $B_2H_6 + 3\,O_2 \longrightarrow B_2O_3 + 3\,H_2O$
(**b**) $B_2H_6 + O_2 \longrightarrow B_2O_3 + 3\,H_2O$
(**c**) $2\,B_2H_6 + 6\,O_2 \longrightarrow 2\,B_2O_3 + 6\,H_2O$
(**d**) $B_2H_6 + 6\,O_2 \longrightarrow 2\,B_2O_3 + 6\,H_2O$

Putting Concepts Together

The interhalogen compound BrF_3 is a volatile, straw-colored liquid. The compound exhibits appreciable electrical conductivity because of autoionization ("solv" refers to BrF_3 as the solvent):

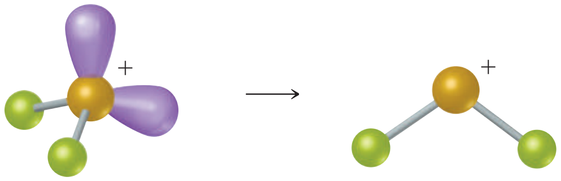
$$2\,BrF_3(l) \rightleftharpoons BrF_2^+(solv) + BrF_4^-(solv)$$

(**a**) What are the molecular structures of the BrF_2^+ and BrF_4^- ions?
(**b**) The electrical conductivity of BrF_3 decreases with increasing temperature. Is the autoionization process exothermic or endothermic?
(**c**) One chemical characteristic of BrF_3 is that it acts as a Lewis acid toward fluoride ions. What do we expect will happen when KBr is dissolved in BrF_3?

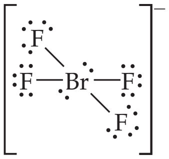
SOLUTION

(**a**) The BrF_2^+ ion has $7 + 2(7) - 1 = 20$ valence-shell electrons. The Lewis structure for the ion is

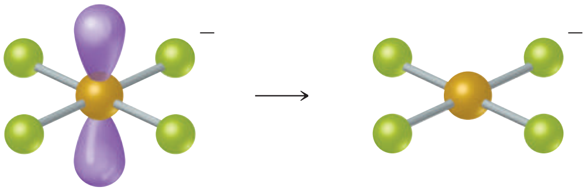
Because there are four electron domains around the central Br atom, the resulting electron domain geometry is tetrahedral (Section 9.2). Because bonding pairs of electrons occupy two of these domains, the molecular geometry is bent:



The BrF_4^- ion has 7 + 4(7) + 1 = 36 electrons, leading to the Lewis structure:

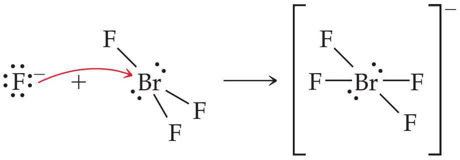


Because there are six electron domains around the central Br atom in this ion, the electron-domain geometry is octahedral. The two nonbonding pairs of electrons are located opposite each other on the octahedron, leading to a square-planar molecular geometry:



(b) The observation that conductivity decreases as temperature increases indicates that fewer ions are present in the solution at the higher temperature. Thus, increasing the temperature causes the equilibrium to shift to the left. According to Le Châtelier's principle, this shift indicates that the reaction is exothermic as it proceeds from left to right. (Section 15.7)

(c) A Lewis acid is an electron-pair acceptor. (Section 16.1) The fluoride ion has four valence-shell electron pairs and can act as a Lewis base (an electron-pair donor). Thus, we can envision the following reaction occurring:



$$F^- \quad + \quad BrF_3 \longrightarrow BrF_4^-$$

Chapter Summary and Key Terms

THE PERIODIC TABLE AND CHEMICAL REACTIONS (SECTION 22.1) The periodic table is useful for organizing and remembering the descriptive chemistry of the elements. Among elements of a given group, size increases with increasing atomic number, and electronegativity and ionization energy decrease. The most nonmetallic elements are found in the upper right portion of the periodic table.

Among the nonmetallic elements, the first member of each group differs dramatically from the other members; it forms a maximum of four bonds to other atoms and exhibits a much greater tendency to form π bonds than the heavier elements in its group.

Because O_2 and H_2O are abundant in our world, we focus on two important and general reaction types as we discuss the nonmetals: oxidation by O_2 and proton-transfer reactions involving H_2O or aqueous solutions.

HYDROGEN (SECTION 22.2) Hydrogen has three isotopes: **protium** (^1_1H), **deuterium** (^2_1H), and **tritium** (^3_1H). Hydrogen is not a member of any particular periodic group, although it is usually placed above lithium. The hydrogen atom can either lose an electron, forming H^+, or gain one, forming H^- (the hydride ion). Because the H—H bond is relatively strong, H_2 is fairly unreactive unless activated by heat or a catalyst. Hydrogen forms a very strong bond to oxygen, so the reactions of H_2 with oxygen-containing compounds usually lead to the formation of H_2O. The $H^+(aq)$ ion is able to oxidize many metals, forming $H_2(g)$. The electrolysis of water also forms $H_2(g)$.

The binary compounds of hydrogen are of three general types: **ionic hydrides** (formed by active metals), **metallic hydrides** (formed by transition metals), and **molecular hydrides** (formed by nonmetals). The ionic hydrides contain the H^- ion; because this ion is extremely basic, ionic hydrides react with H_2O to form H_2 and OH^-.

GROUP 8A: THE NOBLE GASES AND GROUP 7A: HALOGENS (SECTIONS 22.3 AND 22.4) The noble gases (group 8A) exhibit a very limited chemical reactivity because of the exceptional stability of their electron configurations. The xenon fluorides and oxides and KrF_2 are the best-established compounds of the noble gases.

The halogens (group 7A) occur as diatomic molecules. All except fluorine exhibit oxidation states varying from −1 to +7. Fluorine is the most electronegative element, so it is restricted to the oxidation states 0 and −1. The oxidizing power of the element (the tendency to form the −1 oxidation state) decreases as we proceed down the group.

The hydrogen halides are among the most useful compounds of these elements; these gases dissolve in water to form the hydrohalic acids, such as $HCl(aq)$. Hydrofluoric acid reacts with **silica**. The **interhalogens** are compounds formed between two different halogen elements. Chlorine, bromine, and iodine form a series of oxyacids, in which the halogen atom is in a positive oxidation state. These compounds and their associated oxyanions are strong oxidizing agents.

OXYGEN AND THE OTHER GROUP 6A ELEMENTS (SECTIONS 22.5 AND 22.6) Oxygen has two allotropes, O_2 and O_3 (ozone). Ozone is unstable compared to O_2, and it is a stronger oxidizing agent than O_2.

Most reactions of O_2 lead to oxides, compounds in which oxygen is in the -2 oxidation state. The soluble oxides of nonmetals generally produce acidic aqueous solutions; they are called **acidic anhydrides** or **acidic oxides.** In contrast, soluble metal oxides produce basic solutions and are called **basic anhydrides** or **basic oxides**. Many metal oxides that are insoluble in water dissolve in acid, accompanied by the formation of H_2O.

Peroxides contain O—O bonds and oxygen in the -1 oxidation state. Peroxides are unstable, decomposing to O_2 and oxides. In such reactions, peroxides are simultaneously oxidized and reduced, a process called **disproportionation**. Superoxides contain the O_2^- ion in which oxygen is in the $-\frac{1}{2}$ oxidation state.

Sulfur is the most important of the other group 6A elements. It has several allotropic forms; the most stable one at room temperature consists of S_8 rings. Sulfur forms two oxides, SO_2 and SO_3, and both are important atmospheric pollutants. Sulfur trioxide is the anhydride of sulfuric acid, the most important sulfur compound and the most-produced industrial chemical. Sulfuric acid is a strong acid and a good dehydrating agent. Sulfur forms several oxyanions as well, including the SO_3^{2-} (sulfite), SO_4^{2-} (sulfate), and $S_2O_3^{2-}$ (thiosulfate) ions. Sulfur is found combined with many metals as a sulfide, in which sulfur is in the -2 oxidation state. These compounds often react with acids to form hydrogen sulfide (H_2S), which smells like rotten eggs.

NITROGEN AND THE OTHER GROUP 5A ELEMENTS (SECTIONS 22.7 AND 22.8) Nitrogen is found in the atmosphere as N_2 molecules. Molecular nitrogen is chemically very stable because of the strong N≡N bond. Molecular nitrogen can be converted into ammonia via the Haber process. Once the ammonia is made, it can be converted into a variety of different compounds that exhibit nitrogen oxidation states ranging from -3 to $+5$. The most important industrial conversion of ammonia is the **Ostwald process**, in which ammonia is oxidized to nitric acid (HNO_3).

Nitrogen has three important oxides: nitrous oxide (N_2O), nitric oxide (NO), and nitrogen dioxide (NO_2). Nitrous acid (HNO_2) is a weak acid; its conjugate base is the nitrite ion (NO_2^-). Another important nitrogen compound is hydrazine (N_2H_4).

Phosphorus is the most important of the remaining group 5A elements. It occurs in nature as phosphate minerals. Phosphorus has several allotropes, including white phosphorus, which consists of P_4 tetrahedra. In reaction with the halogens, phosphorus forms trihalides PX_3 and pentahalides PX_5. These compounds undergo hydrolysis to produce an oxyacid of phosphorus and HX.

Phosphorus forms two oxides, P_4O_6 and P_4O_{10}. Their corresponding acids, phosphorous acid and phosphoric acid, undergo condensation reactions when heated. Phosphorus compounds are important in biochemistry and as fertilizers. Arsenic, antimony, and bismuth react similarly to phosphorus.

CARBON AND THE OTHER GROUP 4A ELEMENTS (SECTIONS 22.9 AND 22.10) The allotropes of carbon include diamond, graphite, fullerenes, carbon nanotubes, and graphene. Amorphous forms of graphite include **charcoal** and **carbon black**. Carbon forms two common oxides, CO and CO_2. Aqueous solutions of CO_2 produce the weak diprotic acid carbonic acid (H_2CO_3), which is the parent acid of hydrogen carbonate and carbonate salts. Binary compounds of carbon are called **carbides**. Carbides may be ionic, interstitial, or covalent. Calcium carbide (CaC_2) contains the strongly basic acetylide ion (C_2^{2-}), which reacts with water to form acetylene.

The other group 4A elements show great diversity in physical and chemical properties. Silicon, the second most abundant element in Earth's crust, is a semiconductor. It reacts with Cl_2 to form $SiCl_4$, a liquid at room temperature, a reaction that is used to help purify silicon from its native minerals. Silicon forms strong Si—O bonds and therefore occurs in a variety of silicate minerals. Silica is SiO_2; **silicates** consist of SiO_4 tetrahedra, linked together at their vertices to form chains, sheets, or three-dimensional structures. The most common three-dimensional silicate is quartz (SiO_2). **Glass** is an amorphous (noncrystalline) form of SiO_2. Silicones contain O—Si—O chains with organic groups bonded to the Si atoms. Like silicon, germanium is a metalloid; tin and lead are metallic.

BORON (SECTION 22.11) Boron is the only group 3A element that is a nonmetal. It forms a variety of compounds with hydrogen called boron hydrides, or **boranes**. Diborane (B_2H_6) has an unusual structure with two hydrogen atoms that bridge between the two boron atoms. Boranes react with oxygen to form boric oxide (B_2O_3), in which boron is in the $+3$ oxidation state. Boric oxide is the anhydride of boric acid (H_3BO_3). Boric acid readily undergoes condensation reactions.

Exam Prep

EP 22.1 Which description correctly describes a difference between the chemistry of oxygen and sulfur?

(**a**) Oxygen is a nonmetal and sulfur is a metalloid. (**b**) Oxygen can form more than four bonds, whereas sulfur cannot. (**c**) Sulfur has a higher electronegativity than oxygen. (**d**) Oxygen is better able to form π bonds than sulfur.

EP 22.2 When CaC_2 reacts with water, what carbon-containing compound forms? (**a**) CO (**b**) CO_2 (**c**) CH_4 (**d**) C_2H_2 (**e**) H_2CO_3

EP 22.3 What is the oxidation state of the H atom in methane? (**a**) -4 (**b**) -2 (**c**) 0 (**d**) $+1$ (**e**) $+4$

EP 22.4 Which of the elements Na, Rb, F, and Si has the smallest atomic radius? (**a**) F (**b**) Na (**c**) Rb (**d**) Si

EP 22.5 What is the maximum number of electrons hydrogen can have in its valence shell? (**a**) 2 (**b**) 6 (**c**) 8 (**d**) 10

EP 22.6 The steam reforming of methane produces hydrogen and what other product? (**a**) water (**b**) carbon monoxide (**c**) carbon dioxide (**d**) oxygen (**e**) propane

EP 22.7 Which element forms a metallic hydride with hydrogen? (**a**) Sr (**b**) As (**c**) P (**d**) Pd

EP 22.8 Which of the following choices is a metallic hydride? (**a**) BaH_2 (**b**) CuH (**c**) H_2Se (**d**) CsH (**e**) N_2H_2

EP 22.9 Predict the products for the following reaction:

$$Ni(s) + H_2SO_4(aq) \longrightarrow$$

(**a**) $Ni^{2+}(aq) + H_2(g) + SO_4^{2-}(aq)$

(**b**) $NiO(s) + H_2O(l) + SO_2(g)$

(**c**) $NiSO_4(s) + H_2(g)$

(**d**) $NiO_2(s) + H_2O(l) + SO(g)$

EP 22.10 Which of the following statements is or are *true*?

(**i**) Hydrogen has three naturally occurring isotopes.
(**ii**) All the isotopes of hydrogen have very similar properties.
(**iii**) Protium is the most abundant isotope of hydrogen.

(**a**) Only statement i is true. (**b**) Statements ii and iii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 22.11 Compounds containing the XeF_3^+ ion have been characterized. Describe the electron-domain geometry and molecular geometry of this ion.

(**a**) trigonal planar, trigonal planar (**b**) tetrahedral, trigonal pyramidal (**c**) trigonal bipyramidal, T-shaped (**d**) tetrahedral, tetrahedral (**e**) octahedral, square planar

EP 22.12 Which compound has the largest (most positive) oxidation state on the halogen? (**a**) $KXeO_3F$ (**b**) $XeCl_2$ (**c**) $HBrO_3$ (**d**) IF_3

EP 22.13 Which of the following is (are) able to oxidize Cl^-? (**a**) F_2 (**b**) F^- (**c**) both Br_2 and I_2 (**d**) both Br^- and I^-

EP 22.14 Which acid is produced by the reaction of I_2O_5 with water? (**a**) HIO (**b**) HIO_2 (**c**) HIO_3 (**d**) HIO_4

EP 22.15 Which of these oxides is the most acidic? (**a**) N_2O (**b**) SiO_2 (**c**) P_4O_{10} (**d**) P_4O_6

EP 22.16 Predict the molecular geometry of $TeCl_2$. (**a**)tetrahedral (**b**) linear (**c**) trigonal pyramidal (**d**) bent

EP 22.17 The oxidation states of S in $H_2S_2O_7$ is ______ and the oxidation state of N in HNO_2 is ______ (**a**) +3, +3 (**b**) +6, +5 (**c**) +3, +5 (**d**) +6, +3 (**e**) +5, +2

EP 22.18 In power plants, hydrazine is used to prevent corrosion of the metal parts of steam boilers by the O_2 dissolved in the water. The hydrazine reacts with O_2 in water to give $N_2(g)$ and $H_2O(l)$. Write a balanced equation for this reaction.

(**a**) $N_2H_4(aq) + O_2(aq) \longrightarrow N_2(g) + H_2O(l)$

(**b**) $N_2H_4(aq) + O_2(aq) \longrightarrow N_2(g) + 2\,H_2O(l)$

(**c**) $N_2H_6(aq) + 3/2\,O_2(aq) \longrightarrow N_2(g) + 3\,H_2O(l)$

(**d**) $2\,N_2H_6(aq) + 3\,O_2(aq) \longrightarrow 2\,N_2(g) + 6\,H_2O(l)$

EP 22.19 Which of the following statements is or are *true*?

(**i**) Trigonal bipyramidal molecular structures, with 5 atoms about the center atom, can form with either N or P as the center atom.

(**ii**) The properties of the group 5A elements are very similar to each other.

(**iii**) Compounds in which P is in the +5 oxidation state are much stronger oxidizing agents compared to analogous N-containing compounds.

(**a**) Only statement i is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) None of the statements is true.

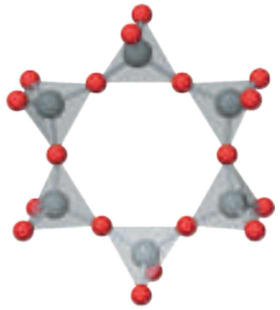
EP 22.20 Which oxyacid is produced when PF_3 reacts with water? (**a**) H_3FO_3 (**b**) H_3FO_4 (**c**) H_3PO_3 (**d**) H_3PO_4

EP 22.21 Which compound is a carbide? (**a**) SiC (**b**) $NaHCO_3$ (**c**) CO_2 (**d**) C_2H_2 (**e**) C_{60}

EP 22.22 What is the most common oxidation state of silicon in its compounds? (**a**) −4 (**b**) +1 (**c**) +2 (**d**) +3 (**e**) +4

EP 22.23 The mineral talc, also known as talcum powder, has the formula $Mg_3(Si_2O_5)_2(OH)_2$. What type of silicate structure does it form? (**a**) a 3D network like diamond (**b**) chains of linked SiO_4 tetrahedra (**c**) sheets of linked SiO_4 tetrahedra (**d**) chains of —Si—O—Si—O— atoms with Mg(II) and hydroxide counterions

EP 22.24 In the mineral beryl, six silicate tetrahedra are connected to form a ring as shown here. The negative charge of this polyanion is balanced by Be^{2+} and Al^{3+} cations. If elemental analysis gives a Be:Si ratio of 1:2 and an Al:Si ratio of 1:3, then what is the empirical formula of beryl? (**a**) $Be_2Al_3Si_6O_{19}$ (**b**) $Be_3Al_2(SiO_4)_6$ (**c**) $Be_3Al_2Si_6O_{18}$ (**d**) $BeAl_2Si_6O_{15}$



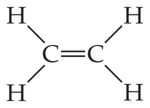
Beryl

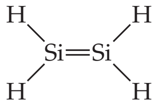
EP 22.25 Polymers that have an O—Si—O backbone and hydrocarbon groups on the Si are ______. The linking of SiO_4 tetrahedra in three dimensions forms ______. SiO_4 tetrahedra linked in sheets or chains form ______. (**a**) silicates, quartz, silicones (**b**) silicates, silicones, quartz (**c**) quartz, silicones, silicates (**d**) quartz, silicates, silicones (**e**) silicones, quartz, silicates

Exercises

Visualizing Concepts

22.1 Which statement identifies which of these two compounds is more stable and explains why? [Section 22.1]





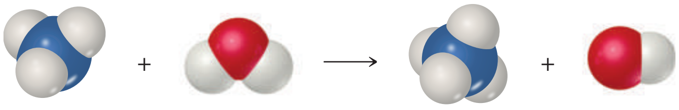
(**a**) The carbon compound because C is less electronegative than Si

(**b**) The silicon compound because Si forms stronger sigma bonds than C

(**c**) The carbon compound because C forms stronger multiple bonds than Si

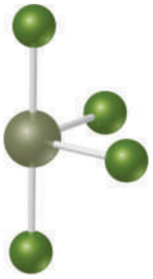
(**d**) The silicon compound because Si forms stronger pi bonds than C

22.2 (**a**) Identify the *type* of chemical reaction represented by the following diagram. (**b**) Place appropriate charges on the species on both sides of the equation. (**c**) Write the chemical equation for the reaction. [Section 22.1]



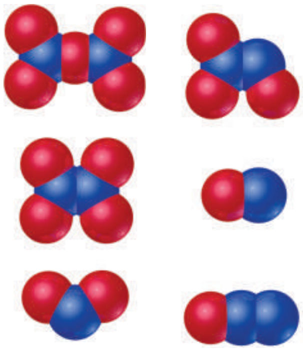
22.3 Which of the following species (there may be more than one) is/are likely to have the structure shown here?

(**a**) XeF_4 (**b**) BrF_4^+ (**c**) SiF_4 (**d**) $TeCl_4$ (**e**) $HClO_4$ (The colors do not reflect atom identities.) [Sections 22.3, 22.4, 22.6, and 22.10]

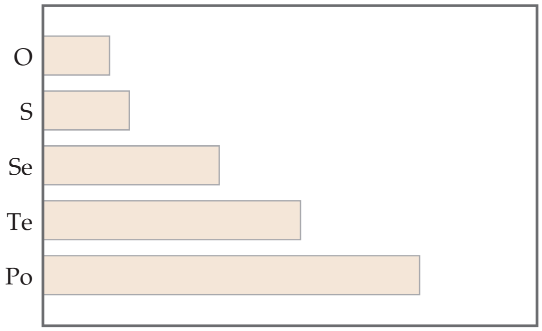


22.4 You have two glass bottles, one containing oxygen and one filled with nitrogen. How could you determine which one is which? [Sections 22.5 and 22.7]

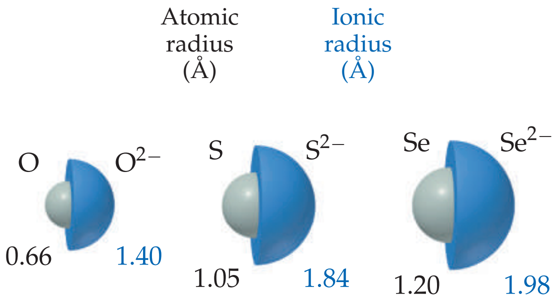
22.5 Write the molecular formula and Lewis structure for each of the following oxides of nitrogen: [Section 22.7]



22.6 Which property of the group 6A elements might be the one depicted in the graph shown here? (**a**) electronegativity (**b**) first ionization energy (**c**) density (**d**) X—X single-bond enthalpy (**e**) electron affinity [Sections 22.5 and 22.6]



22.7 Identify the true statements concerning the atoms and ions of the group 6A elements. [Sections 22.5 and 22.6]



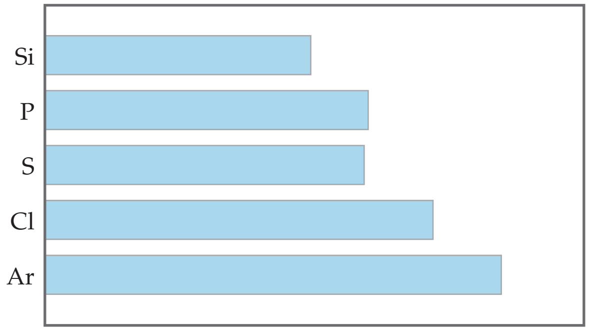
(**a**) The ionic radii are larger than the atomic radii because the ions have more electrons than their corresponding atoms.

(**b**) Atomic radii increase going down the group because of increasing nuclear charge.

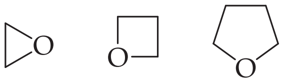
(**c**) The ionic radii increase going down the group because of the increase in the principal quantum number of outermost electrons.

(**d**) Of these ions, Se^{2-} is the strongest base in water because it is the largest.

22.8 Which property of the third-row nonmetallic elements might be the one depicted in the graphic? (**a**) first ionization energy (**b**) atomic radius (**c**) electronegativity (**d**) melting point (**e**) X—X single-bond enthalpy [Sections 22.3, 22.4, 22.6, 22.8, and 22.10]



22.9 Which of the following compounds would you expect to be the most generally reactive, and why? (Each corner in these structures represents a CH_2 group.) [Section 22.8]



22.10 (**a**) Draw the Lewis structures for at least four species that have the general formula

$$[:X\equiv Y:]^n$$

where X and Y may be the same or different and n may have a value from +1 to −2. (**b**) Which of the compounds is likely to be the strongest Brønsted base? Explain. [Sections 22.1, 22.7, and 22.9]

Periodic Trends and Chemical Reactions (Section 22.1)

22.11 Identify each of the following elements as a metal, nonmetal, or metalloid: (**a**) phosphorus, (**b**) strontium, (**c**) manganese, (**d**) selenium, (**e**) sodium, (**f**) krypton.

22.12 Identify each of the following elements as a metal, nonmetal, or metalloid: (**a**) gallium, (**b**) molybdenum, (**c**) tellurium, (**d**) arsenic, (**e**) xenon, (**f**) ruthenium.

22.13 Consider the elements O, Ba, Co, Be, Br, and Se. From this list, select the element that (**a**) is most electronegative, (**b**) exhibits a maximum oxidation state of +7, (**c**) loses an electron most readily, (**d**) forms π bonds most readily, (**e**) is a transition metal, (**f**) is a liquid at room temperature and pressure.

22.14 Consider the elements Li, K, Cl, C, Ne, and Ar. From this list, select the element that (**a**) is most electronegative, (**b**) has the greatest metallic character, (**c**) most readily forms a positive ion, (**d**) has the smallest atomic radius, (**e**) forms π bonds most readily, (**f**) has multiple allotropes.

22.15 Which of the following statements are *true*?

(**a**) Both nitrogen and phosphorus can form a pentafluoride compound.

(**b**) Although CO is a well-known compound, SiO does not exist under ordinary conditions.

(**c**) Cl_2 is easier to oxidize than I_2.

(**d**) At room temperature, the stable form of oxygen is O_2, whereas that of sulfur is S_8.

22.16 Which of the following statements are *true*?

(**a**) Si can form an ion with six fluorine atoms, SiF_6^{2-}, whereas carbon cannot.

(**b**) Si can form three stable compounds containing two Si atoms each, Si_2H_2, Si_2H_4, and Si_2H_6.

(**c**) In HNO_3 and H_3PO_4 the central atoms, N and P, have different oxidation states.

(**d**) S is more electronegative than Se.

22.17 Complete and balance the following equations:

(**a**) $NaOCH_3(s) + H_2O(l) \longrightarrow$

(**b**) $CuO(s) + HNO_3(aq) \longrightarrow$

(**c**) $WO_3(s) + H_2(g) \xrightarrow{\Delta}$

(**d**) $NH_2OH(l) + O_2(g) \longrightarrow$

(**e**) $Al_4C_3(s) + H_2O(l) \longrightarrow$

22.18 Complete and balance the following equations:

(**a**) $Mg_3N_2(s) + H_2O(l) \longrightarrow$

(**b**) $C_3H_7OH(l) + O_2(g) \longrightarrow$

(**c**) $MnO_2(s) + C(s) \xrightarrow{\Delta}$

(**d**) $AlP(s) + H_2O(l) \longrightarrow$

(**e**) $Na_2S(s) + HCl(aq) \longrightarrow$

Hydrogen, the Noble Gases, and the Halogens (Sections 22.2, 22.3, and 22.4)

22.19 (**a**) Give the names and chemical symbols for the three isotopes of hydrogen. (**b**) List the isotopes in order of decreasing natural abundance. (**c**) Which hydrogen isotope is radioactive? (**d**) Write the nuclear equation for the radioactive decay of this isotope.

22.20 The physical properties of D_2O differ from those of H_2O because

(**a**) D has a different electron configuration than O.

(**b**) D is radioactive.

(**c**) D forms stronger bonds with O than H does.

(**d**) D is much more massive than H.

22.21 Give a reason why hydrogen might be placed with the group 1A elements of the periodic table.

22.22 Give a reason why hydrogen might be placed with the group 7A elements of the periodic table.

22.23 Complete and balance the following equations:

(**a**) $NaH(s) + H_2O(l) \longrightarrow$

(**b**) $Fe(s) + H_2SO_4(aq) \longrightarrow$

(**c**) $H_2(g) + Br_2(g) \longrightarrow$

(**d**) $Na(l) + H_2(g) \longrightarrow$

(**e**) $PbO(s) + H_2(g) \longrightarrow$

22.24 Write balanced equations for each of the following reactions (some of these are analogous to reactions shown in the chapter). (**a**) Aluminum metal reacts with acids to form hydrogen gas. (**b**) Steam reacts with magnesium metal to give magnesium oxide and hydrogen. (**c**) Manganese(IV) oxide is reduced to manganese(II) oxide by hydrogen gas. (**d**) Calcium hydride reacts with water to generate hydrogen gas.

22.25 Identify the following hydrides as ionic, metallic, or molecular: (**a**) BaH_2, (**b**) H_2Te, (**c**) $TiH_{1.7}$.

22.26 Identify the following hydrides as ionic, metallic, or molecular: (**a**) B_2H_6, (**b**) RbH, (**c**) $Th_4H_{1.5}$.

22.27 Describe two characteristics of hydrogen that are favorable for its use as a general energy source in vehicles.

22.28 The H_2/O_2 fuel cell converts elemental hydrogen and oxygen into water, producing, theoretically, 1.23 V. What is the most sustainable way to obtain hydrogen to run a large number of fuel cells? Explain.

22.29 Why does xenon form stable compounds with fluorine, whereas argon does not?

22.30 A friend tells you that the “neon” in neon signs is a compound of neon and aluminum. Can your friend be correct? Explain.

22.31 Write the chemical formula for each of the following, and indicate the oxidation state of the halogen or noble-gas atom in each: (**a**) calcium hypobromite, (**b**) bromic acid, (**c**) xenon trioxide, (**d**) perchlorate ion, (**e**) iodous acid, (**f**) iodine pentafluoride.

22.32 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the halogen or noble-gas atom in each: (**a**) chlorate ion, (**b**) hydroiodic acid, (**c**) iodine trichloride, (**d**) sodium hypochlorite, (**e**) perchloric acid, (**f**) xenon tetrafluoride.

22.33 Name the following compounds and assign oxidation states to the halogens in them: (**a**) $Fe(ClO_3)_3$, (**b**) $HClO_2$, (**c**) XeF_6, (**d**) BrF_5, (**e**) $XeOF_4$, (**f**) HIO_3.

22.34 Name the following compounds and assign oxidation states to the halogens in them: (**a**) $KClO_3$, (**b**) $Ca(IO_3)_2$, (**c**) $AlCl_3$, (**d**) $HBrO_3$, (**e**) H_5IO_6, (**f**) XeF_4.

22.35 Explain each of the following observations: (**a**) At room temperature I_2 is a solid, Br_2 is a liquid, and Cl_2 and F_2 are both gases. (**b**) F_2 cannot be prepared by electrolytic oxidation of aqueous F^- solutions. (**c**) The boiling point of HF is much higher than those of the other hydrogen halides. (**d**) The halogens decrease in oxidizing power in the order $F_2 > Cl_2 > Br_2 > I_2$.

22.36 Explain the following observations: (**a**) For a given oxidation state, the acid strength of the oxyacid in aqueous solution decreases in the order chlorine > bromine > iodine. (**b**) Hydrofluoric acid cannot be stored in glass bottles. (**c**) HI cannot be prepared by treating NaI with sulfuric acid. (**d**) The interhalogen ICl_3 is known, but $BrCl_3$ is not.

Oxygen and the Other Group 6A Elements (Sections 22.5 and 22.6)

22.37 Write balanced equations for each of the following reactions. (**a**) When mercury(II) oxide is heated, it decomposes to form O_2 and mercury metal. (**b**) When copper(II) nitrate is heated strongly, it decomposes to form copper(II) oxide, nitrogen dioxide, and oxygen. (**c**) Lead(II) sulfide, $PbS(s)$, reacts with ozone to form $PbSO_4(s)$ and $O_2(g)$. (**d**) When heated in air, $ZnS(s)$ is converted to ZnO. (**e**) Potassium peroxide reacts with $CO_2(g)$ to give potassium carbonate and O_2. (**f**) Oxygen is converted to ozone in the upper atmosphere.

22.38 Complete and balance the following equations:

(**a**) $CaO(s) + H_2O(l) \longrightarrow$
(**b**) $Al_2O_3(s) + H^+(aq) \longrightarrow$
(**c**) $Na_2O_2(s) + H_2O(l) \longrightarrow$
(**d**) $N_2O_3(g) + H_2O(l) \longrightarrow$
(**e**) $KO_2(s) + H_2O(l) \longrightarrow$
(**f**) $NO(g) + O_3(g) \longrightarrow$

22.39 Predict whether each of the following oxides is acidic, basic, amphoteric, or neutral: (**a**) NO_2, (**b**) CO_2, (**c**) Al_2O_3, (**d**) CaO.

22.40 Select the more acidic member of each of the following pairs: (**a**) Mn_2O_7 and MnO_2, (**b**) SnO and SnO_2, (**c**) SO_2 and SO_3, (**d**) SiO_2 and SO_2, (**e**) Ga_2O_3 and In_2O_3, (**f**) SO_2 and SeO_2.

22.41 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (**a**) selenous acid, (**b**) potassium hydrogen sulfite, (**c**) hydrogen telluride, (**d**) carbon disulfide, (**e**) calcium sulfate, (**f**) cadmium sulfide, (**g**) zinc telluride.

22.42 Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (**a**) sulfur tetrachloride, (**b**) selenium trioxide, (**c**) sodium thiosulfate, (**d**) hydrogen sulfide, (**e**) sulfuric acid, (**f**) sulfur dioxide, (**g**) mercury telluride.

22.43 In aqueous solution, hydrogen sulfide reduces (**a**) Fe^{3+} to Fe^{2+}, (**b**) Br_2 to Br^-, (**c**) MnO_4^- to Mn^{2+}, (**d**) HNO_3 to NO_2. In all cases, under appropriate conditions, the product is elemental sulfur. Write a balanced net ionic equation for each reaction.

22.44 An aqueous solution of SO_2 reduces (**a**) aqueous $KMnO_4$ to $MnSO_4(aq)$, (**b**) acidic aqueous $K_2Cr_2O_7$ to aqueous Cr^{3+}, (**c**) aqueous $Hg_2(NO_3)_2$ to mercury metal. Write balanced equations for these reactions.

22.45 Write the Lewis structure for each of the following species, and indicate the structure of each: (**a**) SeO_3^{2-}; (**b**) S_2Cl_2; (**c**) chlorosulfonic acid, HSO_3Cl (chlorine is bonded to sulfur).

22.46 The SF_5^- ion is formed when $SF_4(g)$ reacts with fluoride salts containing large cations, such as $CsF(s)$. Draw the Lewis structures for SF_4 and SF_5^-, and predict the molecular structure of each.

22.47 Write a balanced equation for each of the following reactions: (**a**) Sulfur dioxide reacts with water. (**b**) Solid zinc sulfide reacts with hydrochloric acid. (**c**) Elemental sulfur reacts with sulfite ion to form thiosulfate. (**d**) Sulfur trioxide is dissolved in sulfuric acid.

22.48 Write a balanced equation for each of the following reactions. (You may have to guess at one or more of the reaction products, but you should be able to make a reasonable guess, based on your study of this chapter.) (**a**) Hydrogen selenide can be prepared by reaction of an aqueous acid solution on aluminum selenide. (**b**) Sodium thiosulfate is used to remove excess Cl_2 from chlorine-bleached fabrics. The thiosulfate ion forms SO_4^{2-} and elemental sulfur, while Cl_2 is reduced to Cl^-.

Nitrogen and the Other Group 5A Elements (Sections 22.7 and 22.8)

22.49 Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (**a**) sodium nitrite, (**b**) ammonia, (**c**) nitrous oxide, (**d**) sodium cyanide, (**e**) nitric acid, (**f**) nitrogen dioxide, (**g**) nitrogen, (**h**) boron nitride.

22.50 Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (**a**) nitric oxide, (**b**) hydrazine, (**c**) potassium cyanide, (**d**) sodium nitrite, (**e**) ammonium chloride, (**f**) lithium nitride.

22.51 Write the Lewis structure for each of the following species, describe its geometry, and indicate the oxidation state of the nitrogen: (**a**) HNO_2, (**b**) N_3^-, (**c**) $N_2H_5^+$, (**d**) NO_3^-.

22.52 Write the Lewis structure for each of the following species, describe its geometry, and indicate the oxidation state of the nitrogen: (**a**) NH_4^+, (**b**) NO_2^-, (**c**) N_2O, (**d**) NO_2.

22.53 Complete and balance the following equations:

(**a**) $Mg_3N_2(s) + H_2O(l) \longrightarrow$

(**b**) $NO(g) + O_2(g) \longrightarrow$

(**c**) $N_2O_5(g) + H_2O(l) \longrightarrow$

(**d**) $NH_3(aq) + H^+(aq) \longrightarrow$

(**e**) $N_2H_4(l) + O_2(g) \longrightarrow$

Which ones of these are redox reactions?

22.54 Write a balanced net ionic equation for each of the following reactions: (**a**) Dilute nitric acid reacts with zinc metal with formation of nitrous oxide. (**b**) Concentrated nitric acid reacts with sulfur with formation of nitrogen dioxide. (**c**) Concentrated nitric acid oxidizes sulfur dioxide with formation of nitric oxide. (**d**) Hydrazine is burned in excess fluorine gas, forming NF_3. (**e**) Hydrazine reduces CrO_4^{2-} to $Cr(OH)_4^-$ in base (hydrazine is oxidized to N_2).

22.55 Write complete balanced half-reactions for (**a**) oxidation of nitrous acid to nitrate ion in acidic solution, (**b**) oxidation of N_2 to N_2O in acidic solution.

22.56 Write complete balanced half-reactions for (**a**) reduction of nitrate ion to NO in acidic solution, (**b**) oxidation of HNO_2 to NO_2 in acidic solution.

22.57 Write a molecular formula for each compound, and indicate the oxidation state of the group 5A element in each formula: (**a**) phosphorous acid, (**b**) pyrophosphoric acid, (**c**) antimony trichloride, (**d**) magnesium arsenide, (**e**) diphosphorus pentoxide, (**f**) sodium phosphate.

22.58 Write a chemical formula for each compound or ion, and indicate the oxidation state of the group 5A element in each formula: (**a**) phosphate ion, (**b**) arsenous acid, (**c**) antimony(III) sulfide, (**d**) calcium dihydrogen phosphate, (**e**) potassium phosphide, (**f**) gallium arsenide.

22.59 Account for the following observations: (**a**) Phosphorus forms a pentachloride, but nitrogen does not. (**b**) H_3PO_2 is a monoprotic acid. (**c**) Phosphonium salts, such as PH_4Cl, can be formed under anhydrous conditions, but they cannot be made in aqueous solution. (**d**) White phosphorus is more reactive than red phosphorus.

22.60 Account for the following observations: (**a**) H_3PO_3 is a diprotic acid. (**b**) Nitric acid is a strong acid, whereas phosphoric acid is weak. (**c**) Phosphate rock is ineffective as a phosphate fertilizer. (**d**) Phosphorus does not exist at room temperature as diatomic molecules, but nitrogen does. (**e**) Solutions of Na_3PO_4 are quite basic.

22.61 Write a balanced equation for each of the following reactions: (**a**) preparation of white phosphorus from calcium phosphate, (**b**) hydrolysis of PBr_3, (**c**) reduction of PBr_3 to P_4 in the gas phase, using H_2.

22.62 Write a balanced equation for each of the following reactions: (**a**) hydrolysis of PCl_5, (**b**) dehydration of phosphoric acid (also called orthophosphoric acid) to form pyrophosphoric acid, (**c**) reaction of P_4O_{10} with water.

Carbon, the Other Group 4A Elements, and Boron (Sections 22.9, 22.10, and 22.11)

22.63 Give the chemical formula for (**a**) hydrocyanic acid, (**b**) nickel tetracarbonyl, (**c**) barium bicarbonate, (**d**) calcium acetylide, (**e**) potassium carbonate.

22.64 Give the chemical formula for (**a**) carbonic acid, (**b**) sodium cyanide, (**c**) potassium hydrogen carbonate, (**d**) acetylene, (**e**) iron pentacarbonyl.

22.65 Complete and balance the following equations:

(**a**) $ZnCO_3(s) \xrightarrow{\Delta}$

(**b**) $BaC_2(s) + H_2O(l) \longrightarrow$

(**c**) $C_2H_2(g) + O_2(g) \longrightarrow$

(**d**) $CS_2(g) + O_2(g) \longrightarrow$

(**e**) $Ca(CN)_2(s) + HBr(aq) \longrightarrow$

22.66 Complete and balance the following equations:

(**a**) $CO_2(g) + OH^-(aq) \longrightarrow$

(**b**) $NaHCO_3(s) + H^+(aq) \longrightarrow$

(**c**) $CaO(s) + C(s) \xrightarrow{\Delta}$

(**d**) $C(s) + H_2O(g) \xrightarrow{\Delta}$

(**e**) $CuO(s) + CO(g) \longrightarrow$

22.67 Write a balanced equation for each of the following reactions: (**a**) Hydrogen cyanide is formed commercially by passing a mixture of methane, ammonia, and air over a catalyst at 800 °C. Water is a byproduct of the reaction. (**b**) Baking soda reacts with acids to produce carbon dioxide gas. (**c**) When barium carbonate reacts in air with sulfur dioxide, barium sulfate and carbon dioxide form.

22.68 Write a balanced equation for each of the following reactions: (**a**) Burning magnesium metal in a carbon dioxide atmosphere reduces the CO_2 to carbon. (**b**) In photosynthesis, solar energy is used to produce glucose ($C_6H_{12}O_6$) and O_2 from carbon dioxide and water. (**c**) When carbonate salts dissolve in water, they produce basic solutions.

22.69 Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or of boron in each: (**a**) boric acid, (**b**) silicon tetrabromide, (**c**) lead(II) chloride, (**d**) sodium tetraborate decahydrate (borax), (**e**) boric oxide, (**f**) germanium dioxide.

22.70 Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or of boron in each: (**a**) silicon dioxide, (**b**) germanium tetrachloride, (**c**) sodium borohydride, (**d**) stannous chloride, (**e**) diborane, (**f**) boron trichloride.

22.71 Select the member of group 4A that best fits each description: (**a**) has the lowest first ionization energy, (**b**) is found in oxidation states ranging from -4 to $+4$, (**c**) is most abundant in Earth's crust.

22.72 Select the member of group 4A that best fits each description: (**a**) forms chains to the greatest extent, (**b**) forms the most basic oxide, (**c**) is a metalloid that can form 2+ ions.

22.73 (**a**) What is the characteristic geometry about silicon in all silicate minerals? (**b**) Metasilicic acid has the empirical formula H_2SiO_3. Which of the structures shown in Figure 22.32 would you expect metasilicic acid to have?

22.74 Speculate as to why carbon forms carbonate rather than silicate analogs.

22.75 (**a**) Determine the number of calcium ions in the chemical formula of the mineral hardystonite, $Ca_xZn(Si_2O_7)$. (**b**) Determine the number of hydroxide ions in the chemical formula of the mineral pyrophyllite, $Al_2(Si_2O_5)_2(OH)_x$.

22.76 (**a**) Determine the number of sodium ions in the chemical formula of albite, $Na_xAlSi_3O_8$. (**b**) Determine the number of hydroxide ions in the chemical formula of tremolite, $Ca_2Mg_5(Si_4O_{11})_2(OH)_x$.

22.77 (**a**) How does the structure of diborane (B_2H_6) differ from that of ethane (C_2H_6)? (**b**) Explain why diborane adopts the geometry that it does. (**c**) What is the significance of the statement that the hydrogen atoms in diborane are described as "hydridic"?

22.78 Write a balanced equation for each of the following reactions: (**a**) Diborane reacts with water to form boric acid and molecular hydrogen. (**b**) Upon heating, boric acid undergoes a condensation reaction to form tetraboric acid. (**c**) Boron oxide dissolves in water to give a solution of boric acid.

Additional Exercises

22.79 Indicate whether each of the following statements is *true* or *false*. (**a**) $H_2(g)$ and $D_2(g)$ are allotropic forms of hydrogen. (**b**) ClF_3 is an interhalogen compound. (**c**) $MgO(s)$ is an acidic anhydride. (**d**) $SO_2(g)$ is an acidic anhydride. (**e**) $2\,H_3PO_4(l) \longrightarrow H_4P_2O_7(l) + H_2O(g)$ is an example of a condensation reaction. (**f**) Tritium is an isotope of the element hydrogen. (**g**) $2\,SO_2(g) + O_2(g) \longrightarrow 2\,SO_3(g)$ is an example of a disproportionation reaction.

22.80 Although the ClO_4^- and IO_4^- ions have been known for a long time, BrO_4^- was not synthesized until 1965. The ion was synthesized by oxidizing the bromate ion with xenon difluoride, producing xenon, hydrofluoric acid, and the perbromate ion. (**a**) Write the balanced equation for this reaction. (**b**) What are the oxidation states of Br in the Br-containing species in this reaction?

22.81 Write a balanced equation for the reaction of each of the following compounds with water: (**a**) $SO_2(g)$, (**b**) $Cl_2O_7(g)$, (**c**) $Na_2O_2(s)$, (**d**) $BaC_2(s)$, (**e**) $RbO_2(s)$ (**f**) $Mg_3N_2(s)$, (**g**) $NaH(s)$.

22.82 What is the anhydride for each of the following acids? (**a**) H_2SO_4 (**b**) $HClO_3$ (**c**) HNO_2 (**d**) H_2CO_3 (**e**) H_3PO_4

22.83 Hydrogen peroxide is capable of oxidizing (**a**) hydrazine to N_2 and H_2O, (**b**) SO_2 to SO_4^{2-}, (**c**) NO_2^- to NO_3^-, (**d**) $H_2S(g)$ to $S(s)$, (**e**) Fe^{2+} to Fe^{3+}. Write a balanced net ionic equation for each of these redox reactions.

22.84 A sulfuric acid plant produces a considerable amount of heat. This heat is used to generate electricity, which helps reduce operating costs. The synthesis of H_2SO_4 consists of three main chemical processes: (**i**) oxidation of S to SO_2, (**ii**) oxidation of SO_2 to SO_3, (**iii**) the dissolving of SO_3 in H_2SO_4 and the subsequent reaction with water to form H_2SO_4. (**a**) If the third process produces 130 kJ/mol, how much heat is produced in preparing a mole of H_2SO_4 from a mole of S? (**b**) How much heat is produced in preparing 5000 pounds of H_2SO_4?

22.85 (**a**) What is the oxidation state of P in PO_4^{3-} and of N in NO_3^-? (**b**) Why doesn't N form a stable NO_4^{3-} ion analogous to P?

22.86 (**a**) The P_4, P_4O_6, and P_4O_{10} molecules have a common structural feature of four P atoms arranged in a tetrahedron (Figures 22.25 and 22.26). Does this mean that the bonding between the P atoms is the same in all these cases? (**b**) Sodium trimetaphosphate ($Na_3P_3O_9$) and sodium tetrametaphosphate ($Na_4P_4O_{12}$) are used as water-softening agents. They contain cyclic $P_3O_9^{3-}$ and $P_4O_{12}^{4-}$ ions, respectively. Propose reasonable structures for these ions.

22.87 Write a balanced chemical reaction for the condensation reaction between H_3PO_4 molecules to form $H_5P_3O_{10}$.

22.88 Ultrapure germanium, like silicon, is used in semiconductors. Germanium of "ordinary" purity is prepared by the high-temperature reduction of GeO_2 with carbon. The Ge is converted to $GeCl_4$ by treatment with Cl_2 and then purified by distillation; $GeCl_4$ is then hydrolyzed in water to GeO_2 and reduced to the elemental form with H_2. The element is then zone refined. Write a balanced chemical equation for each of the chemical transformations in the course of forming ultrapure Ge from GeO_2.

22.89 When aluminum replaces up to half of the silicon atoms in SiO_2, a mineral class called feldspars results. The feldspars are the most abundant rock-forming minerals, comprising about 50% of the minerals in Earth's crust. Orthoclase is a feldspar in which Al replaces one-fourth of the Si atoms of SiO_2, and charge balance is completed by K^+ ions. Determine the chemical formula for orthoclase.

22.90 (**a**) Determine the charge of the aluminosilicate ion whose composition is $AlSi_3O_{10}$. (**b**) Using Figure 22.32, propose a reasonable description of the structure of this aluminosilicate.

22.91 (**a**) How many grams of H_2 can be stored in 100.0 kg of the alloy FeTi if the hydride $FeTiH_2$ is formed? (**b**) What volume does this quantity of H_2 occupy at STP? (**c**) If this quantity of hydrogen was combusted in air to produce liquid water, how much energy could be produced?

22.92 Using the thermochemical data in Table 22.1 and Appendix C, calculate the average Xe—F bond enthalpies in XeF_2, XeF_4, and XeF_6, respectively. What is the significance of the trend in these quantities?

22.93 Hydrogen gas has a higher fuel value than natural gas on a mass basis but not on a volume basis. Thus, hydrogen is not competitive with natural gas as a fuel transported long distances through pipelines. Calculate the heats of combustion of H_2 and CH_4 (the principal component of natural gas) (**a**) per mole of each, (**b**) per gram of each, (**c**) per cubic meter of each at STP. Assume $H_2O(l)$ as a product.

22.94 Using ΔG_f° for ozone from Appendix C, calculate the equilibrium constant for Equation 22.22 at 298.0 K, assuming no electrical input.

22.95 The solubility of Cl_2 in 100 g of water at STP is 310 cm^3. Assume that this quantity of Cl_2 is dissolved and equilibrated as follows:

$$Cl_2(aq) + H_2O \rightleftharpoons Cl^-(aq) + HClO(aq) + H^+(aq)$$

(**a**) If the equilibrium constant for this reaction is 4.7×10^{-4}, calculate the equilibrium concentration of HClO formed. (**b**) What is the pH of the final solution?

22.96 When ammonium perchlorate decomposes thermally, the products of the reaction are $N_2(g)$, $O_2(g)$, $H_2O(g)$, and $HCl(g)$. (**a**) Write a balanced equation for the reaction. (*Hint:* You might find it easier to use fractional coefficients for the products.) (**b**) Calculate the enthalpy change in the reaction per mole of NH_4ClO_4. The standard enthalpy of formation of $NH_4ClO_4(s)$ is −295.8 kJ. (**c**) When $NH_4ClO_4(s)$ is employed in solid-fuel booster rockets, it is packed with powdered aluminum. Given the high temperature needed for $NH_4ClO_4(s)$ decomposition and what the products of the reaction are, what role does the aluminum play? (**d**) Calculate the volume of all the gases that would be produced at STP, assuming complete reaction of one pound of ammonium perchlorate.

22.97 The dissolved oxygen present in any highly pressurized, high-temperature steam boiler can be extremely corrosive to its metal parts. Hydrazine, which is completely miscible with water, can be added to remove oxygen by reacting with it to form nitrogen and water. (**a**) Write the balanced equation for the reaction between gaseous hydrazine and oxygen. (**b**) Calculate the enthalpy change accompanying this reaction. (**c**) Oxygen in air dissolves in water to the extent of 9.1 ppm at 20 °C at sea level. How many grams of hydrazine are required to react with all the oxygen in 3.0×10^4 L (the volume of a small swimming pool) under these conditions?

22.98 One method proposed for removing SO_2 from the flue gases of power plants involves reaction with aqueous H_2S. Elemental sulfur is the product. (**a**) Write a balanced chemical equation for the reaction. (**b**) What volume of H_2S at 27 °C and 760 torr would be required to remove the SO_2 formed by burning 2.0 tons of coal containing 3.5% S by mass? (**c**) What mass of elemental sulfur is produced? Assume that all reactions are 100% efficient.

22.99 The maximum allowable concentration of $H_2S(g)$ in air is 20 mg per kilogram of air (20 ppm by mass). How many grams of FeS would be required to react with hydrochloric acid to produce this concentration at 1.00 atm and 25 °C in an average room measuring 12 ft × 20 ft × 8 ft? (Under these conditions, the average molar mass of air is 29.0 g/mol.)

22.100 The standard heats of formation of $H_2O(g)$, $H_2S(g)$, $H_2Se(g)$, and $H_2Te(g)$ are −241.8, −20.17, +29.7, and +99.6 kJ/mol, respectively. The enthalpies necessary to convert the elements in their standard states to one mole of gaseous atoms are 248, 277, 227, and 197 kJ/mol of atoms for O, S, Se, and Te, respectively. The enthalpy for dissociation of H_2 is 436 kJ/mol. Calculate the average H—O, H—S, H—Se, and H—Te bond enthalpies, and comment on their trend.

22.101 Manganese silicide has the empirical formula MnSi and melts at 1280 °C. It is insoluble in water but does dissolve in aqueous HF. (**a**) What type of compound do you expect MnSi to be: metallic, molecular, covalent-network, or ionic? (**b**) Write a likely balanced chemical equation for the reaction of MnSi with concentrated aqueous HF.

22.102 Hydrazine has been employed as a reducing agent for metals. Using standard reduction potentials, predict whether the following metals can be reduced to the metallic state by hydrazine under standard conditions in acidic solution: (**a**) Fe^{2+}, (**b**) Sn^{2+}, (**c**) Cu^{2+}, (**d**) Ag^+, (**e**) Cr^{3+}, (**f**) Co^{3+}.

22.103 Both dimethylhydrazine, $(CH_3)_2NNH_2$, and methylhydrazine, CH_3NHNH_2, have been used as rocket fuels. When dinitrogen tetroxide (N_2O_4) is used as the oxidizer, the products are H_2O, CO_2, and N_2. If the thrust of the rocket depends on the volume of the products produced, which of the substituted hydrazines produces a greater thrust per gram total mass of oxidizer plus fuel? Assume that both fuels generate the same temperature and that $H_2O(g)$ is formed.

22.104 Borazine, $(BH)_3(NH)_3$, is an analog of C_6H_6, benzene. It can be prepared from the reaction of diborane with ammonia, with hydrogen as another product; or from lithium borohydride and ammonium chloride, with lithium chloride and hydrogen as the other products. (**a**) Write balanced chemical equations for the production of borazine using both synthetic methods. (**b**) Draw the Lewis dot structure of borazine. (**c**) How many grams of borazine can be prepared from 2.00 L of ammonia at STP, assuming diborane is in excess?

Design an Experiment

You are given samples of five substances. At room temperature, three are colorless gases, one is a colorless liquid, and one is a white solid. You are told that the substances are NF_3, PF_3, PCl_3, PF_5, and PCl_5. Let's design experiments to determine which substance is which, using concepts from this and earlier chapters.

(**a**) Assuming that you don't have access to either the Internet or a handbook of chemistry (as is the case during your exams!), design experiments that would allow you to identify the substances. (**b**)Which of the substances could undergo reactions to add more atoms around the central atom? What types of reactions might you choose to test this hypothesis? (**c**) Based on what you know about intermolecular forces, which of the substances is likely the solid?

TRANSITION METALS AND COORDINATION CHEMISTRY

▲ **WATER LILIES AND THE JAPANESE BRIDGE** was painted by Claude Monet in 1899.

WHAT'S AHEAD

23.1 ▶ The Transition Metals Examine the physical properties, electron configurations, oxidation states, and magnetic properties of the *transition metals*.

23.2 ▶ Transition-Metal Complexes Introduce the concepts of *metal complexes* and *ligands* and provide a brief history of the development of *coordination chemistry*.

23.3 ▶ Common Ligands in Coordination Chemistry Explore some of the common geometries found in coordination complexes and how the geometries relate to the *coordination numbers* of the complexes.

23.4 ▶ Nomenclature and Isomerism in Coordination Chemistry Define the nomenclature used for naming metal complexes and become familiar with the concept of *isomerism*, where two compounds have the same composition but different structures.

23.5 ▶ Color and Magnetism in Coordination Chemistry Discover the underlying causes of color in coordination compounds, emphasizing the visible portion of the electromagnetic spectrum and the notion of *complementary colors*. We also see that many transition-metal complexes are paramagnetic because they contain unpaired electrons.

23.6 ▶ Crystal-Field Theory Apply *crystal-field theory* to explain some of the interesting spectral and magnetic properties of coordination compounds.

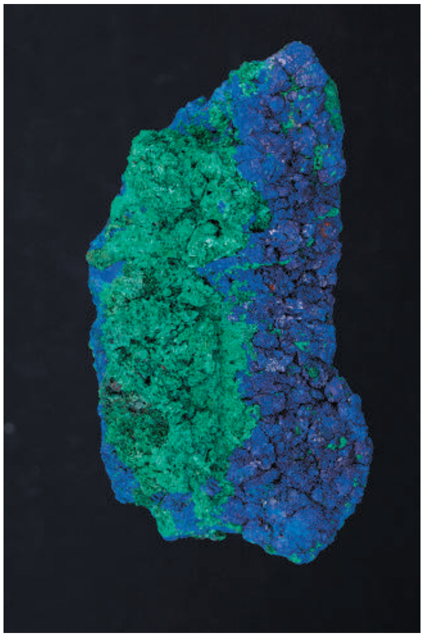
The colors of our world are beautiful, but to a chemist they are also informative—providing insights into the structure and bonding of matter. Compounds of the transition metals constitute an important group of colored substances, including the characteristic red color of oxygenated human blood. The red color is due to an iron-containing protein called hemoglobin that is found in red blood cells.

The colors generated by transition-metal compounds are among the most common we encounter in our world. Some transition-metal compounds are used as pigments; others produce the colors in glass and precious gems. The use of vivid green, yellow, and blue colors in the paintings of impressionists like Monet, Cezanne, and van Gogh was made possible by the development of synthetic pigments in the 1800s. Three such pigments used extensively by the impressionists were cobalt blue, $CoAl_2O_4$; chrome yellow, $PbCrO_4$; and emerald green, $Cu_4(CH_3COO)_2(AsO_2)_6$. In each case, the presence of a transition-metal ion is responsible for the color of the pigment—Co^{2+} in cobalt blue, Cr^{6+} in chrome yellow, and Cu^{2+} in emerald green. Unfortunately, emerald green also contains arsenic, which makes it toxic, and its use as a pigment was discontinued in the early 20th century.

The color of a given transition-metal compound depends on not only the transition-metal ion, but also the identity and geometry of the ions and/or molecules that surround it. To appreciate the importance of the transition-metal ion surroundings, consider the colors of the minerals azurite, $Cu_3(CO_3)_2(OH)_2$, and malachite, $Cu_2(CO_3)(OH)_2$ (**Figure 23.1**). Both minerals contain Cu^{2+} ions coordinated by carbonate and hydroxide ions, but subtle differences in the local surroundings of the Cu^{2+} ion lead to the contrasting colors of these two minerals.

The importance of transition metals is not limited to biology and use as a source of color. Transition metals and their alloys are used as structural materials to make coins and jewelry, and as electronic conductors in wires and electronic devices. The presence of partially filled *d*-orbitals allows transition-metal compounds to act as catalysts and magnets. In earlier chapters, we saw that metal ions can function as Lewis acids, forming covalent bonds with molecules and ions that act as Lewis bases. (Section 16.1) We have previously encountered many ions and compounds that result from such interactions. We first mentioned hemoglobin in the "Chemistry and Life" box on "Sickle-Cell Anemia." (Section 13.6) In our discussion of solubility of ionic substances, we saw the formation of complex ions, such as $[Ag(NH_3)_2]^+$. (Section 17.5)

In this chapter, we take a closer look at many aspects of the transition-metal elements, including the rich and important chemistry associated with such complex assemblies of metal ions surrounded by molecules and ions. Metal compounds of this kind are called *coordination compounds*, and the branch of chemistry that focuses on them is called *coordination chemistry*.



▲ **Figure 23.1** **Crystals of blue azurite and green malachite.** These semiprecious stones were ground up and used as pigments in the Middle Ages and Renaissance, but they were eventually replaced with blue and green pigments that have superior chemical stability.

Learning Objectives

When you finish Section 23.1, you should be able to:

- Predict the physical properties of transition metals based on their position in the periodic table.
- Determine the electron configuration of a transition-metal ion.
- Determine the oxidation state of a transition-metal ion in a compound.
- Describe the different magnetic properties that transition metals can exhibit.

23.1 | The Transition Metals

The part of the periodic table in which the *d* orbitals are being filled as we move left to right across a row is the home of the transition metals (**Figure 23.2**). (Section 6.8)

With some exceptions (such as platinum and gold), metallic elements are found in nature as solid inorganic compounds called **minerals**. Notice from **Table 23.1** that minerals are identified by common names rather than chemical names.

Most transition metals in minerals have oxidation states (Section 4.4) ranging from +1 to +4. To obtain a pure metal from its mineral, various chemical processes must be performed to reduce the metal to its elemental form (oxidation state = 0). **Metallurgy** is the science and technology of extracting metals from their natural sources and preparing them for practical use. It usually involves several steps: (1) mining, that is, removing the relevant *ore* (a mixture of minerals) from the ground, (2) concentrating the ore or otherwise preparing it for further treatment, (3) reducing the ore to obtain the free metal, (4) purifying the metal, and (5) mixing it with other elements to modify its properties. This last process produces an *alloy*, a metallic material composed of two or more elements. (Section 12.2)

*Abbreviations for crystal structures are: hcp = hexagonal close packed, fcc = face-centered cubic, bcc = body-centered cubic. (Section 12.2)

**Manganese has a more complex crystal structure.

Physical Properties

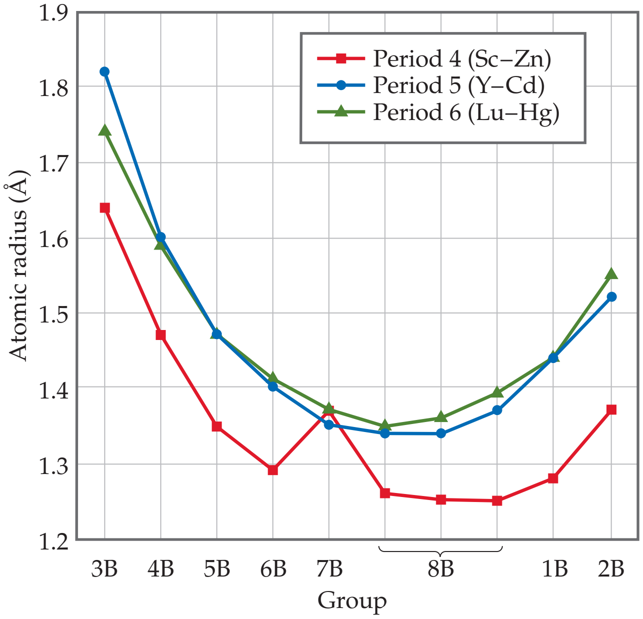
Some physical properties of the period 4 (also known as "first-row") transition metals are listed in **Table 23.2**. The properties of the heavier transition metals vary similarly across periods 5 and 6.

Figure 23.3 shows the atomic radius observed in close-packed metallic structures as a function of group number.* The trends seen in the graph are a result of two competing forces. On the one hand, increasing effective nuclear charge favors a decrease in radius as we move left to right across each period. (Section 7.2) On the other hand, the metallic bonding strength increases until we reach the middle of each period and then decreases as we fill antibonding orbitals. (Section 12.3) As a general rule, a bond shortens as it becomes stronger. (Section 8.8) For groups 3B through 6B, these two effects work cooperatively, and the result is a marked decrease in radius. In elements to the right of group 6B, the two effects counteract each other, reducing the decrease and eventually leading to an increase in radius.

In general, atomic radii increase as we move down in a given group in the periodic table because of the increasing principal quantum number of the outer-shell electrons. (Section 7.3) However, Figure 23.3 shows that once we move beyond the group 3B elements, the period 5 and period 6 transition elements in a given group have virtually the same radii. In group 5B, for example, tantalum in period 6 has virtually the same radius as niobium in period 5. This interesting and important effect has its origin in the lanthanide series, elements 57 through 70. The filling of 4*f* orbitals through the lanthanide elements (Figure 6.28) causes a steady increase in the effective nuclear charge, producing a size decrease called the **lanthanide contraction**, which just offsets the increase we expect as we go from period 5 transition metals to period 6. Thus, the period 5 and period 6 transition metals in each group have very similar radii and chemical properties. For example, the group 4B metals zirconium (period 5) and hafnium (period 6) always occur together in nature and are very difficult to separate.

Go Figure

Does the variation in radius of the transition metals follow the same trend as the effective nuclear charge on moving from left to right across the periodic table?



▲ **Figure 23.3** **Radii of transition metals as a function of group number.**

Electron Configurations and Oxidation States

As we saw in Figure 6.28, transition metals owe their location in the periodic table to the filling of the *d* subshells. Many of the chemical and physical properties of transition metals result from the unique characteristics of the *d* orbitals. For a given transition-metal atom, the valence $(n - 1)d$ orbitals are smaller than the corresponding valence *ns* and *np* orbitals. In quantum-mechanical terms, the $(n - 1)d$ orbital wave functions drop off more rapidly as we move away from the nucleus than do the *ns* and *np* orbital wave functions. This characteristic feature of the *d* orbitals limits their interaction with orbitals on neighboring atoms, but not so much that they are insensitive to surrounding atoms. As a result, electrons in these orbitals behave sometimes like valence electrons and sometimes like core electrons. The details depend on location in the periodic table and the atom's environment.

---

* Note that the radii defined in this way, often referred to as metallic radii, differ somewhat from the bonding atomic radii defined in Section 7.3.

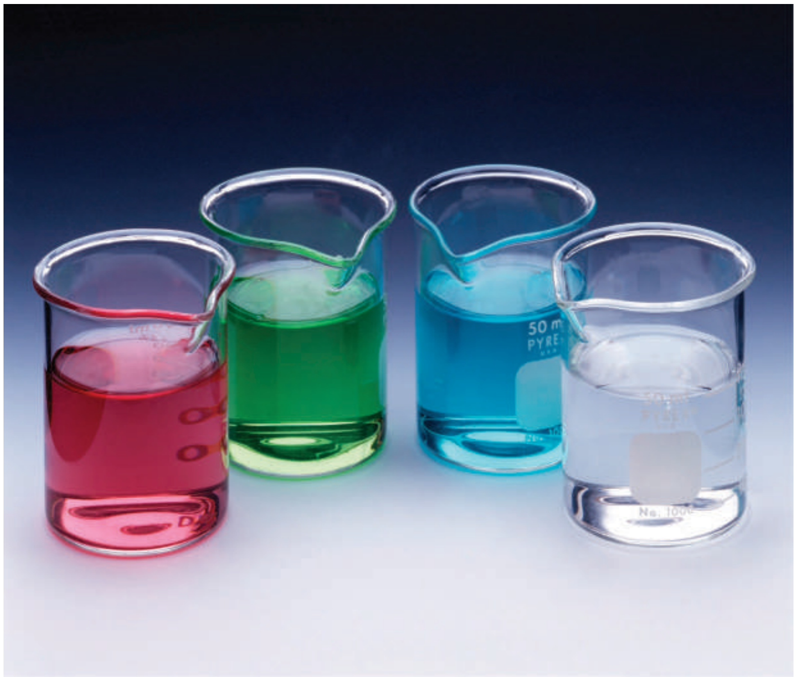
When transition metals are oxidized, *they lose their outer* s *electrons before they lose electrons from the* d *subshell*. (Section 7.4) The electron configuration of Fe is $[\mathrm{Ar}]3d^64s^2$, for example, whereas that of Fe^{2+} is $[\mathrm{Ar}]3d^6$. Formation of Fe^{3+} requires loss of one $3d$ electron, giving $[\mathrm{Ar}]3d^5$. Most transition-metal ions contain partially occupied *d* subshells, which are responsible in large part for three characteristics:

1. Transition metals often have more than one stable oxidation state.
2. Many transition-metal compounds are colored, as shown in **Figure 23.4**.
3. Transition metals and their compounds often exhibit magnetic properties.

Figure 23.5 shows the common nonzero oxidation states for the period 4 transition metals. The +2 oxidation state, which is common for most transition metals, is due to the loss of the two outer 4*s* electrons. This oxidation state is found for all these elements except Sc, where the 3+ ion with an [Ar] configuration is particularly stable.

Oxidation states above +2 are due to successive losses of 3*d* electrons. From Sc through Mn, the maximum oxidation state increases from +3 to +7, equaling in each case the total number of 4*s* plus 3*d* electrons in the atom. Thus, manganese, which has the electron configuration $[\mathrm{Ar}]4s^23d^5$, has a maximum oxidation state of $2 + 5 = +7$. As we move to the right beyond Mn in Figure 23.5, the maximum oxidation state decreases. This decrease is due to the attraction of *d* orbital electrons to the nucleus, which increases faster than the attraction of the *s* orbital electrons to the nucleus as we move left to right across the periodic table. In other words, in each period the *d* electrons become more corelike as the atomic number increases. By the time we get to zinc, it is not possible to remove electrons from the 3*d* orbitals through chemical oxidation.

Go Figure In which transition-metal ion of this group are the 3*d* orbitals completely filled?

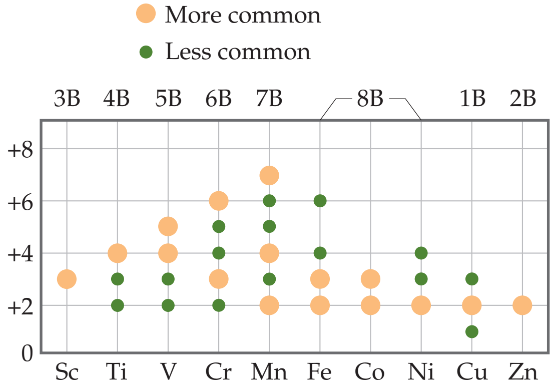


▲ **Figure 23.4 Aqueous solutions of transition-metal ions.** Left to right: Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+}. The counterion is nitrate in all cases.

In the transition metals of periods 5 and 6, the increased size of the 4*d* and 5*d* orbitals makes it possible to attain maximum oxidation states as high as +8, which is achieved in RuO_4 and OsO_4. In general, the maximum oxidation states are found only when the metals are combined with the most electronegative elements, especially O, F, and in some cases Cl.

Go Figure

Are there any ions in this figure for which the 4*s* orbitals are not empty? For which ions are the 3*d* orbitals empty?



▲ **Figure 23.5 Nonzero oxidation states of the period 4 transition metals.**

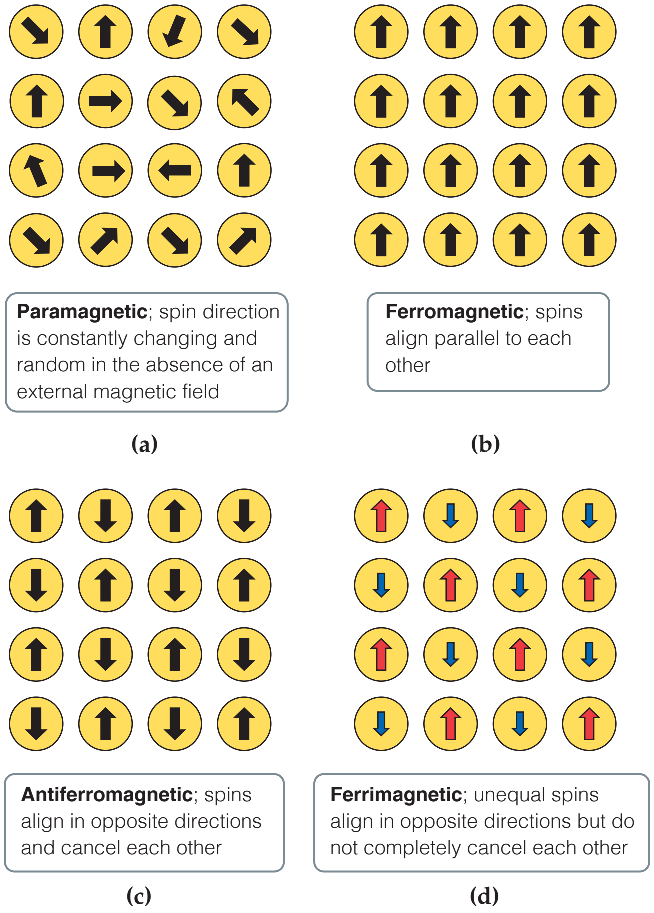
Magnetism

The spin that an electron possesses gives the electron a *magnetic moment*, a property that causes the electron to behave like a tiny magnet. (Section 6.7) In a *diamagnetic* solid, defined as one in which all the electrons in the solid are paired, the spin-up and spin-down electrons cancel one another. (Section 9.8) Diamagnetic substances are generally described as being nonmagnetic, but when a diamagnetic substance is placed in a magnetic field, the motions of the electrons cause the substance to be very weakly repelled by the magnet. In other words, these supposedly nonmagnetic substances do show some very faint magnetic character in the presence of a magnetic field.

A substance in which the atoms or ions have one or more unpaired electrons is *paramagnetic*. (Section 9.8) In a paramagnetic solid, the electrons on one atom or ion do not influence the unpaired electrons on neighboring atoms or ions. As a result, the magnetic moments on the atoms or ions are randomly oriented and constantly changing direction, as shown in **Figure 23.6**(**a**). When a paramagnetic substance is placed in a magnetic field, however, the magnetic moments tend to align parallel to one another, producing a net attractive interaction with the magnet. Thus, unlike a diamagnetic substance, which is weakly repelled by a magnetic field, a paramagnetic substance is attracted to a magnetic field.

Go Figure

Describe how the representation shown for the paramagnetic material would change if the material were placed in a magnetic field.



Paramagnetic; spin direction is constantly changing and random in the absence of an external magnetic field
(a)
Ferromagnetic; spins align parallel to each other
(b)
Antiferromagnetic; spins align in opposite directions and cancel each other
(c)
Ferrimagnetic; unequal spins align in opposite directions but do not completely cancel each other
(d)

▲ **Figure 23.6 The relative orientation of electron spins in various types of magnetic substances.**

When you think of a magnet, you probably picture a simple iron magnet. Iron exhibits **ferromagnetism**, a form of magnetism much stronger than paramagnetism. Ferromagnetism arises when the unpaired electrons of the atoms or ions in a solid are influenced by the orientations of the electrons in neighboring atoms or ions. The most stable (lowest-energy) arrangement is when the spins of electrons on adjacent atoms or ions are aligned in the same direction, as in Figure 23.6(b). When a ferromagnetic solid is placed in a magnetic field, the electrons align strongly in a direction parallel to the magnetic field. The attraction to the magnetic field that results is much stronger than that for a paramagnetic substance.

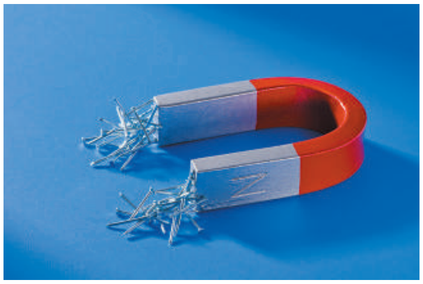
When a ferromagnet is removed from an external magnetic field, the interactions between the electrons cause the ferromagnetic substance to maintain a magnetic moment even in the absence of the external magnetic field. We then refer to it as a *permanent magnet* (**Figure 23.7**).

The only ferromagnetic transition metals are Fe, Co, and Ni, but many alloys also exhibit ferromagnetism, which is in some cases stronger than the ferromagnetism of the pure metals. Particularly powerful ferromagnetism is found in compounds containing both transition metals and lanthanide metals. Two of the most important examples are $SmCo_5$ and $Nd_2Fe_{14}B$.

Two additional types of magnetism involving ordered arrangements of unpaired electrons are depicted in Figure 23.6. In materials that exhibit **antiferromagnetism** [Figure 23.6(c)], the unpaired electrons on a given atom or ion align so that their spins are oriented in the direction opposite the spin direction on neighboring atoms. This means that the spin-up and spin-down electrons cancel each other. Examples of antiferromagnetic substances are chromium metal, FeMn alloys, and such transition-metal oxides as Fe_2O_3, $LaFeO_3$, and MnO.

A substance that exhibits **ferrimagnetism** [Figure 23.6(d)] has both ferromagnetic and antiferromagnetic characteristics. Like an antiferromagnet, the unpaired electrons align so that the spins in adjacent atoms or ions point in opposite directions. However, unlike an antiferromagnet, the net magnetic moments of the spin-up electrons are not fully canceled by the spin-down electrons. This can happen because the magnetic centers have different numbers of unpaired electrons (as is the case for $NiMnO_3$), because the number of magnetic sites aligned in one direction is larger than the number aligned in the other direction ($Y_3Fe_5O_{12}$), or because both of these conditions apply (Fe_3O_4). Because the magnetic moments do not cancel, the properties of ferrimagnetic materials are similar to the properties of ferromagnetic materials.

Ferromagnets, ferrimagnets, and antiferromagnets all become paramagnetic when heated above a critical temperature. This happens when the thermal energy is sufficient to overcome the forces determining the spin directions of the electrons—the special alignment of the electron spins is disrupted above the critical temperature, which varies from substance to substance. This temperature is called the *Curie temperature*, T_C, of the substance for ferromagnets and ferrimagnets and the *Néel temperature*, T_N, for antiferromagnets.



▲ **Figure 23.7 A permanent magnet.** Permanent magnets are made from ferromagnetic and ferrimagnetic materials.

Self-Assessment Exercises

SAE 23.1 Which of the following statements about the transition-metal elements is or are *true*?

(i) Most of the transition metals are found in nature as minerals.
(ii) The atomic radius of a period 6 transition metal is generally very similar to that of the period 5 transition metal immediately above it in the periodic table.
(iii) Transition-metal elements tend to form compounds in which they have negative oxidation states.

(**a**) Only statement i is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

SAE 23.2 How many electrons are in the valence *d* orbitals of ground-state Zn^{2+}? (**a**) 2 (**b**) 6 (**c**) 8 (**d**) 10 (**e**) 12

SAE 23.3 What is the ground-state electron configuration of Mn^{2+}? (**a**) $[Ar]4s^23d^5$ (**b**) $[Ar]3d^5$ (**c**) $[Ar]4s^23d^3$ (**d**) $[Ar]4s^23d^7$

SAE 23.4 What is the oxidation state of chromium in Cr_2O_3? (**a**) −3 (**b**) 0 (**c**) +2 (**d**) +3 (**e**) +6

SAE 23.5 Which of the following transition-metal ions is expected to exhibit paramagnetism? (**a**) Sc^{3+} (**b**) Cu^+ (**c**) Fe^{3+} (**d**) Zn^{2+}

23.2 | Transition-Metal Complexes

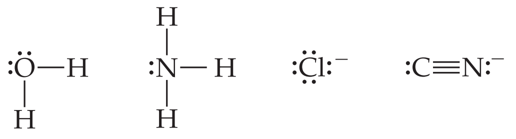
Learning Objectives

When you finish Section 23.2, you should be able to:

- Determine the coordination number and coordination sphere of a transition-metal complex.
- Describe how a metal–ligand bond is formed.

The transition metals occur in many interesting and important molecular forms. Species that are assemblies of a central transition-metal ion bonded to a group of surrounding molecules or ions, such as $[Ag(NH_3)_2]^+$, $[CoCl_4]^{2-}$, and $[Fe(H_2O)_6]^{3+}$, are called **metal complexes**, or merely *complexes*.* If the complex carries a net charge, it is generally called a *complex ion*. (Section 17.5) Compounds that contain complexes are known as **coordination compounds**.

The molecules or ions that bond to the metal ion in a complex are known as **ligands** (from the Latin word *ligare*, "to bind"). There are two NH_3 ligands bonded to Ag^+ in the complex ion $[Ag(NH_3)_2]^+$, for instance, four Cl^- ligands bonded to Co^{2+} in $[CoCl_4]^{2-}$, and six H_2O ligands bonded to Fe^{3+} in $[Fe(H_2O)_6]^{3+}$. Each ligand functions as a Lewis base and so donates a pair of electrons to form the metal–ligand bond. (Section 16.1) Thus, every ligand has at least one lone pair of valence electrons. Four of the most frequently encountered ligands,



illustrate that most ligands are either polar molecules or anions. In forming a complex, the ligands are said to *coordinate* to the metal.

---

* Most of the coordination compounds we examine in this chapter contain transition-metal ions, although ions of other metals can also form complexes.

TABLE 23.3 Properties of Some Ammonia Complexes of Cobalt(III)

Original Formulation	Color	Ions per Formula Unit	"Free" Cl^- Ions per Formula Unit	Modern Formulation
$CoCl_3 \cdot 6\,NH_3$	Orange	4	3	$[Co(NH_3)_6]Cl_3$
$CoCl_3 \cdot 5\,NH_3$	Purple	3	2	$[Co(NH_3)_5Cl]Cl_2$
$CoCl_3 \cdot 4\,NH_3$	Green	2	1	*trans*-$[Co(NH_3)_4Cl_2]Cl$
$CoCl_3 \cdot 4\,NH_3$	Violet	2	1	*cis*-$[Co(NH_3)_4Cl_2]Cl$

Notice that, in writing the formula for complex ions, such as $[Fe(H_2O)_6]^{3+}$, we use square brackets to enclose the metal ion and all of the ligands. The overall charge of the complex ion is written outside the brackets. We expand more on this nomenclature shortly.

The Development of Coordination Chemistry: Werner's Theory

Because compounds of the transition metals are beautifully colored, the chemistry of these elements fascinated chemists even before the periodic table was introduced. During the late 1700s through the 1800s, the many coordination compounds that were isolated and studied had properties that were puzzling in light of the bonding theories prevailing at the time. **Table 23.3**, for example, lists a series of $CoCl_3$–NH_3 compounds that have strikingly different colors. Note that the third and fourth species have different colors, even though the originally assigned formula was the same for both, $CoCl_3 \cdot 4\,NH_3$.

The modern formulations of the compounds, listed in Table 23.3, are based on various lines of experimental evidence. For example, all four compounds are strong electrolytes (Section 4.1) but yield different numbers of ions when dissolved in water. Dissolving $CoCl_3 \cdot 6\,NH_3$ in water yields four ions per formula unit ($[Co(NH_3)_6]^{3+}$ plus three Cl^- ions), whereas $CoCl_3 \cdot 5\,NH_3$ yields only three ions per formula unit ($[Co(NH_3)_5Cl]^{2+}$ and two Cl^- ions). Furthermore, the reaction of the compounds with excess aqueous silver nitrate leads to the precipitation of different amounts of $AgCl(s)$. When $CoCl_3 \cdot 6\,NH_3$ is treated with excess $AgNO_3(aq)$, 3 mol of $AgCl(s)$ precipitate per mole of complex, which means all three Cl^- ions in the complex can react to form $AgCl(s)$. By contrast, when $CoCl_3 \cdot 5\,NH_3$ is treated with excess $AgNO_3(aq)$, only 2 mol of $AgCl(s)$ precipitate per mole of complex, telling us that one of the Cl^- ions in the complex does not react with Ag^+. These results are summarized in Table 23.3.

In 1893, the Swiss chemist Alfred Werner (1866–1919) proposed a theory that successfully explained the observations shown in Table 23.3. In a theory that became the basis for understanding coordination chemistry, Werner proposed that any metal ion exhibits both a primary valence and a secondary valence. The *primary valence* is the oxidation state of the metal, which is +3 for the complexes in Table 23.3. The *secondary valence* is the number of atoms bonded to the metal ion, which is also called the **coordination number**. For these cobalt complexes, Werner deduced a coordination number of 6 with the ligands in an octahedral arrangement (Section 9.1) around the Co^{3+} ion.

Werner's theory provided a beautiful explanation for the results presented in Table 23.3. The NH_3 molecules are ligands bonded to the Co^{3+} ion (through the nitrogen atom as we will see later); if there are fewer than six NH_3 molecules, the remaining ligands are Cl^- ions. The central metal and the ligands bonded to it constitute the **coordination sphere** of the complex.

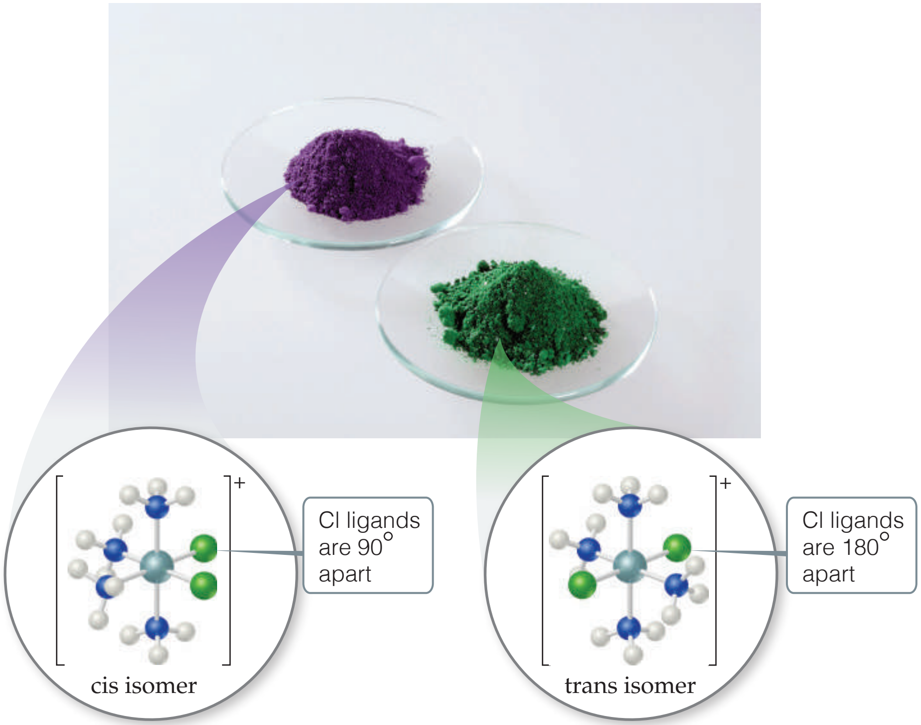
In writing the chemical formula for a coordination compound, Werner suggested using square brackets to signify the makeup of the coordination sphere in any given compound. He therefore proposed that $CoCl_3 \cdot 6\,NH_3$ and $CoCl_3 \cdot 5\,NH_3$ are better written as $[Co(NH_3)_6]Cl_3$ and $[Co(NH_3)_5Cl]Cl_2$, respectively. He further proposed that the chloride ions that are part of the coordination sphere are bonded so tightly that they do not dissociate when the complex is dissolved in water. Thus, dissolving $[Co(NH_3)_5Cl]Cl_2$ in water produces a $[Co(NH_3)_5Cl]^{2+}$ ion and two Cl^- ions.

Werner's ideas also explained why there are two forms of $CoCl_3 \cdot 4\,NH_3$. Using Werner's postulates, we write the formula as $[Co(NH_3)_4Cl_2]Cl$. As shown in **Figure 23.8**, there are two ways to arrange the ligands in the $[Co(NH_3)_4Cl_2]^+$ complex, called the *cis* and *trans* forms. In the cis form, the two chloride ligands occupy adjacent vertices of the octahedral arrangement. In *trans*-$[Co(NH_3)_4Cl_2]^+$, the two chlorides are opposite each other. It is this difference in positions of the Cl ligands that leads to two compounds, one violet and one green.

The insight Werner provided into the bonding in coordination compounds is even more remarkable when we realize that his theory predated Lewis's ideas of covalent bonding by more than 20 years! Because of his tremendous contributions to coordination chemistry, Werner was awarded the 1913 Nobel Prize in Chemistry.

Go Figure

Is there another way to arrange the chloride ions in the $[Co(NH_3)_4Cl_2]^+$ ion besides the two shown in this figure?



▲ **Figure 23.8** **Isomers of $[Co(NH_3)_4Cl_2]^+$.** The cis isomer is violet, whereas the trans isomer is green.

Sample Exercise 23.1

Identifying the Coordination Sphere of a Complex

Palladium(II) tends to form complexes with coordination number 4. A compound has the composition $PdCl_2 \cdot 3\,NH_3$. (**a**) Write the formula for this compound that best shows the coordination structure. (**b**) When an aqueous solution of the compound is treated with excess $AgNO_3(aq)$, how many moles of $AgCl(s)$ are formed per mole of $PdCl_2 \cdot 3\,NH_3$?

SOLUTION

Analyze We are given the coordination number of Pd(II) and a chemical formula indicating that the complex contains NH_3 and Cl^-. We are asked to determine (**a**) which ligands are attached to Pd(II) in the compound and (**b**) how the compound behaves toward $AgNO_3$ in aqueous solution.

Plan (**a**) Because of their charge, the Cl^- ions can be either in the coordination sphere, where they are bonded directly to the metal, or outside the coordination sphere, where they are bonded ionically to the complex. The electrically neutral NH_3 ligands must be in the coordination sphere, and we are told that four ligands are bonded to the Pd(II) ion. (**b**) Any chlorides in the coordination sphere do not precipitate as AgCl.

Solve

(**a**) By analogy to the ammonia complexes of cobalt(III) shown in Figure 23.8, we predict that the three NH_3 are ligands attached to the Pd(II) ion. The fourth ligand around Pd(II) is one chloride ion. The second chloride ion is not a ligand; it serves only as a *counterion* (a noncoordinating ion that balances charge) in the compound. We conclude that the formula showing the structure best is $[Pd(NH_3)_3Cl]Cl$.

(b) Because only the non-ligand Cl^- can react with Ag^+, we expect to produce 1 mol of $AgCl(s)$ per mole of complex. The balanced equation is

$$[Pd(NH_3)_3Cl]Cl(aq) + AgNO_3(aq) \longrightarrow [Pd(NH_3)_3Cl]NO_3(aq) + AgCl(s)$$

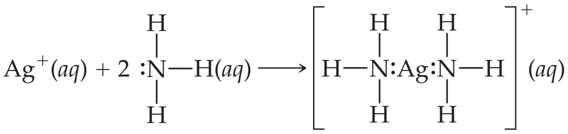
This is a metathesis reaction (Section 4.2) in which one of the cations is the $[Pd(NH_3)_3Cl]^+$ complex ion.

▶ Practice Exercise

Predict the number of ions produced per formula unit when the compound $CoCl_2 \cdot 6\,H_2O$ dissolves in water to form an aqueous solution.

The Metal–Ligand Bond

The bond between a ligand and a metal ion forms as a result of a Lewis acid–base interaction. (Section 16.1) Because the ligands have available pairs of electrons, they can function as Lewis bases (electron-pair donors). Metal ions (particularly transition-metal ions) have empty valence orbitals, so they can act as Lewis acids (electron-pair acceptors). We can picture the bond between the metal ion and ligand as the result of their sharing a pair of electrons initially on the ligand:



$$Ag^+(aq) + 2\,:NH_3(aq) \longrightarrow [H_3N:Ag:NH_3]^+(aq)$$

The formation of metal–ligand bonds can markedly alter the properties we observe for the metal ion. A metal complex is a distinct chemical species that has physical and chemical properties different from those of the metal ion and ligands from which it is formed. As one example, **Figure 23.9** shows the color change that occurs when aqueous solutions of NCS^- (colorless) and Fe^{3+} (yellow) are mixed, forming $[Fe(H_2O)_5NCS]^{2+}$.

Complex formation can also significantly change other properties of metal ions, such as their ease of oxidation or reduction. Silver ion, for example, is readily reduced in water:

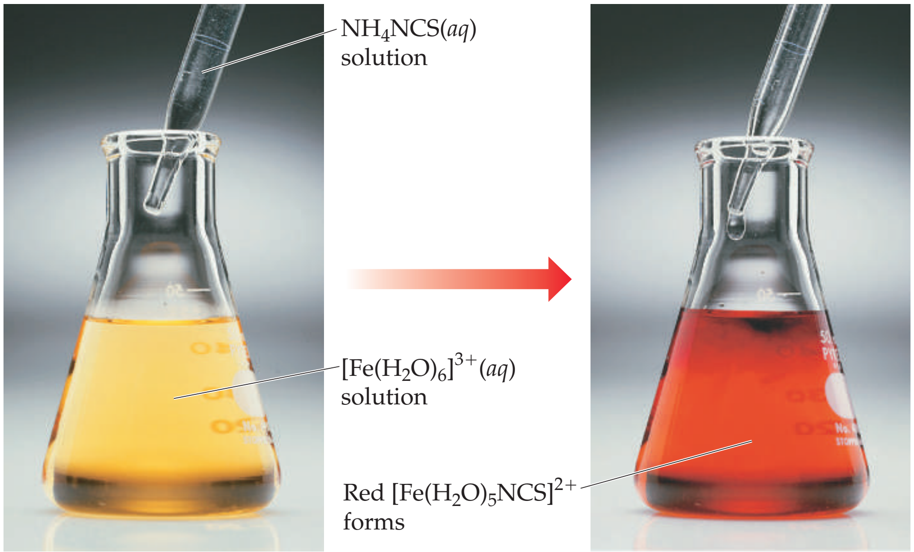
$$Ag^+(aq) + e^- \longrightarrow Ag(s) \qquad E^\circ_{red} = +0.799\ V \tag{23.2}$$

By comparison, the $[Ag(CN)_2]^-$ ion is much harder to reduce (more negative value of E°_{red}) because complexation by CN^- ions stabilizes silver in the +1 oxidation state:

$$[Ag(CN)_2]^-(aq) + e^- \longrightarrow Ag(s) + 2\,CN^-(aq) \quad E^\circ_{red} = -0.31\ V \tag{23.3}$$

Go Figure

Does the coordination number of iron change during this reaction? Does the oxidation number of iron change?



$NH_4NCS(aq)$ solution
$[Fe(H_2O)_6]^{3+}(aq)$ solution
Red $[Fe(H_2O)_5NCS]^{2+}$ forms

▲ **Figure 23.9 The reaction between $[Fe(H_2O)_6]^{3+}(aq)$ and $NCS^-(aq)$.**

Hydrated metal ions are complexes in which the ligand is water. Thus, $Fe^{3+}(aq)$ consists largely of $[Fe(H_2O)_6]^{3+}$. (Section 16.9) It is important to realize that ligands can undergo reaction. For example, we saw in Figure 16.18 that a water molecule in $[Fe(H_2O)_6]^{3+}(aq)$ can be deprotonated to yield $[Fe(H_2O)_5OH]^{2+}(aq)$ and $H^+(aq)$. The iron ion retains its oxidation state; the coordinated hydroxide ligand, with a 1− charge, reduces the complex charge to 2+. Ligands can also be displaced from the coordination sphere by other ligands, if the incoming ligands bind more strongly to the metal ion than the original ones. For example, ligands such as NH_3, NCS^-, and CN^- can replace H_2O in the coordination sphere of metal ions, as we saw in Figure 23.9.

Charges, Coordination Numbers, and Geometries

The charge of a complex is the sum of the charges on the metal and on the ligands. In $[Cu(NH_3)_4]SO_4$ we can deduce the charge on the complex ion because we know that the sulfate ion has a 2− charge. Because the compound is electrically neutral, the complex ion must have a 2+ charge: $[Cu(NH_3)_4]^{2+}$. We can then use the charge of the complex ion to deduce the oxidation state of copper. Because the NH_3 ligands are uncharged molecules, the oxidation state of copper must be +2:

$$\begin{array}{c} +2 + 4(0) = +2 \\ \downarrow \qquad \downarrow \qquad \swarrow \\ [Cu(NH_3)_4]^{2+} \end{array}$$

Recall that the number of atoms directly bonded to the metal atom in a complex is the *coordination number* of the complex. Thus, the copper ion in $[Cu(NH_3)_4]^{2+}$ has a coordination number of 4. Similarly, the silver ion in $[Ag(NH_3)_2]^+$ has a coordination number of 2, and the cobalt ion has a coordination number of 6 in all four complexes in Table 23.3.

Some metal ions exhibit only one observed coordination number. The coordination number of chromium(III) and cobalt(III) is invariably 6, for example, and that of platinum(II) is always 4. For most metals, however, the coordination number can be different for different ligands. In these complexes, the most common coordination numbers are 4 and 6.

The coordination number of a metal ion is often influenced by the relative sizes of the metal ion and the ligands. As the ligand gets larger, fewer of them can coordinate to the metal ion. Thus, iron(III) is able to coordinate to six fluorides in $[FeF_6]^{3-}$ but to only four chlorides in $[FeCl_4]^-$. Ligands that transfer substantial negative charge to the metal also produce reduced coordination numbers. For example, six ammonia molecules can coordinate to nickel(II), forming $[Ni(NH_3)_6]^{2+}$, but only four cyanide ions can coordinate to this ion, forming $[Ni(CN)_4]^{2-}$.

Sample Exercise 23.2

Determining the Oxidation State of a Metal in a Complex

What is the oxidation state of the metal in $[Rh(NH_3)_5Cl](NO_3)_2$?

SOLUTION

Analyze We are given the chemical formula of a coordination compound and asked to determine the oxidation state of its metal atom.

Plan To determine the oxidation state of Rh, we need to figure out what charges are contributed by the other groups. The overall charge is zero, so the oxidation state of the metal must balance the charge due to the rest of the compound.

Solve The NO_3 group is the nitrate anion, which has a 1− charge. The NH_3 ligands carry zero charge, and the Cl is a coordinated chloride ion, which has a 1− charge. The sum of all the charges must be zero:

$$\begin{array}{c} x + 5(0) + (-1) + 2(-1) = 0 \\ \searrow \qquad \downarrow \qquad \downarrow \qquad \swarrow \\ [Rh(NH_3)_5Cl](NO_3)_2 \end{array}$$

The oxidation state of rhodium, x, must therefore be +3.

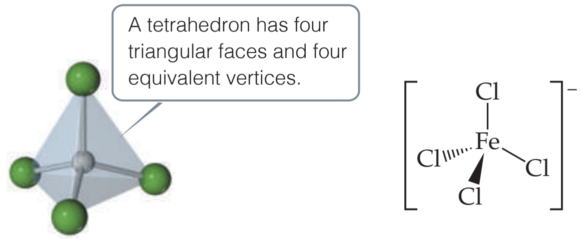
Practice Exercise

What is the charge of the complex formed by a platinum(II) metal ion to which two ammonia molecules and two bromide ions are coordinated?

The most common coordination geometries for coordination complexes are shown in **Figure 23.10**. Complexes in which the coordination number is 4 have two possible geometries—tetrahedral and square planar. The tetrahedral geometry is the more common of the two and is especially prevalent among nontransition metals [as we saw in our discussion of the VSEPR model (Section 9.2)]. The square-planar geometry is characteristic of most transition-metal ions with eight *d* electrons in the valence shell, such as platinum(II) and gold(III). Complexes with a coordination number of 6 almost always have an octahedral geometry. Even though the octahedron can be drawn as a square with one ligand above and another below the plane, all six vertices are equivalent.

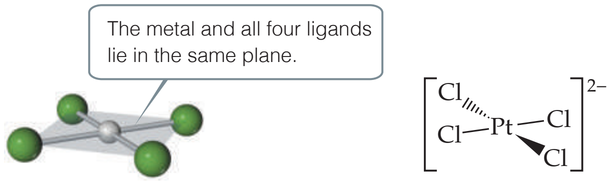
Go Figure

In the drawings on the right-hand side, what does the solid wedge connecting atoms represent? What does the dashed wedge connecting atoms represent?



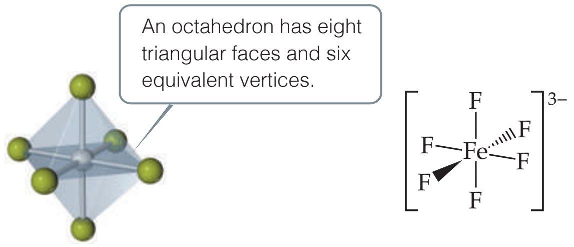
A tetrahedron has four triangular faces and four equivalent vertices.

Tetrahedral geometry



The metal and all four ligands lie in the same plane.

Square-planar geometry



An octahedron has eight triangular faces and six equivalent vertices.

Octahedral geometry

▲ **Figure 23.10 Common geometries of coordination complexes.** In complexes having coordination number 4, the geometry is typically either tetrahedral or square planar. In complexes having coordination number 6, the geometry is nearly always octahedral.

Self-Assessment Exercises

SAE 23.6 In the complex $[Co(NH_3)_5Br]Br_2$, the oxidation state of the cobalt atom is ______ and the coordination number is ______.
(**a**) 0, 6 (**b**) 0, 8 (**c**) +2, 6 (**d**) +3, 5 (**e**) +3, 6

SAE 23.7 Which of the following statements about the complex $[Zn(NH_3)_4]Cl_2$ is *false*?

(**a**) The coordination number of the complex is 4.
(**b**) When an NH_3 ligand binds to the zinc atom, it is acting as a Lewis base.
(**c**) The geometry of the complex ion is octahedral.
(**d**) The oxidation state of the zinc atom is +2.
(**e**) Both of the Cl ions in the complex could be precipitated using $AgNO_3(aq)$.

23.3 Common Ligands in Coordination Chemistry

Learning Objectives

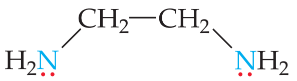
When you finish Section 23.3, you should be able to:

- Distinguish between monodentate, bidentate, and polydentate ligands.
- For common ligands, identify the number and type of donor atoms that bind to the central metal atom in a coordination complex.

The ligand atom that binds to the central metal ion in a coordination complex is called the **donor atom** of the ligand. Ligands having only one donor atom are called **monodentate ligands** (from the Latin, meaning "one-toothed"). These ligands are able to occupy only one site in a coordination sphere. Ligands having two donor atoms are **bidentate ligands** ("two-toothed"), and those having three or more donor atoms are **polydentate ligands** ("many-toothed"). In both bidentate and polydentate species, the multiple donor atoms can simultaneously bond to the metal ion, thereby occupying two or more sites in a coordination sphere. **Table 23.4** gives examples of all three types of ligands.

Because they appear to grasp the metal between two or more donor atoms, bidentate and polydentate ligands are also known as **chelating agents** (pronounced "KEE-lay-ting"; from the Greek *chele*, "claw").

One common chelating agent is the bidentate ligand *ethylenediamine*, $C_2N_2H_8$, which is denoted *en*:



$H_2\ddot{N}-CH_2-CH_2-\ddot{N}H_2$

Each of the nitrogen atoms in an en ligand has one nonbonding electron pair. Thus, each of the N atoms can serve as a donor atom to a metal, and because they are sufficiently far apart, they can bind to the metal ion in adjacent positions. The complex ion $[Co(en)_3]^{3+}$, which contains three ethylenediamine ligands in the octahedral coordination sphere of

TABLE 23.4 Some Common Ligands

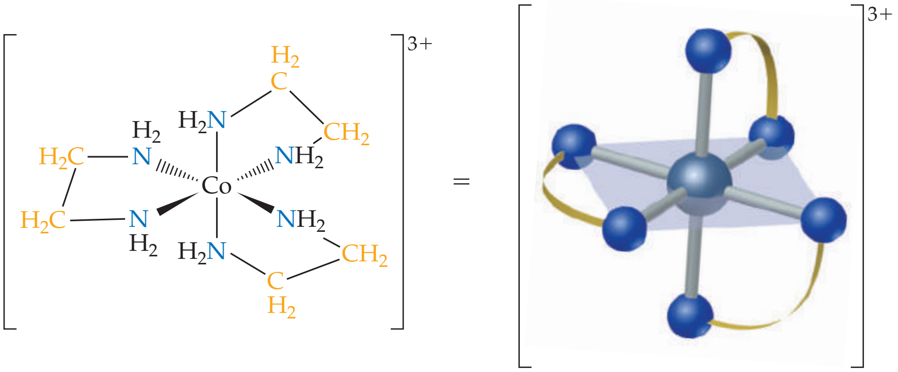
Ligand Type	Examples							
Monodentate	$H_2\ddot{O}:$	Water	$:\ddot{F}:^-$	Fluoride ion	$[:C\equiv N:]^-$	Cyanide ion	$[:\ddot{O}-H]^-$	Hydroxide ion
	$:NH_3$	Ammonia	$:\ddot{Cl}:^-$	Chloride ion	$\underbrace{[:\ddot{S}=C=\ddot{N}:]^-}_{\text{or}}$	Thiocyanate ion	$\underbrace{[:\ddot{O}-N=\ddot{O}:]^-}_{\text{or}}$	Nitrite ion
Bidentate	 Ethylenediamine (en)		 Bipyridine (bipy or bpy)		 *Ortho*-phenanthroline (*o*-phen)		 Oxalate ion	 Carbonate ion
Polydentate	 Diethylenetriamine		 Triphosphate ion					
	 Ethylenediaminetetraacetate ion ($EDTA^{4-}$)							

cobalt(III), is shown in **Figure 23.11**. Notice that in the image on the right the en is written in a shorthand notation as two nitrogen atoms connected by an arc.

The ethylenediaminetetraacetate ion, $[EDTA]^{4-}$, is an important polydentate ligand that has six donor atoms (two N atoms and four O atoms). It can wrap around a metal ion using all six donor atoms, as shown in **Figure 23.12**, although it sometimes binds to a metal using only five of its donor atoms.

In general, the complexes formed by chelating ligands (that is, bidentate and polydentate ligands) are more stable than the complexes formed by related monodentate ligands. The equilibrium formation constants for $[Ni(NH_3)_6]^{2+}$ and $[Ni(en)_3]^{2+}$ illustrate this observation:

$$[Ni(H_2O)_6]^{2+}(aq) + 6\,NH_3(aq) \rightleftharpoons [Ni(NH_3)_6]^{2+}(aq) + 6\,H_2O(l)$$
$$K_f = 1.2 \times 10^9 \qquad [23.4]$$



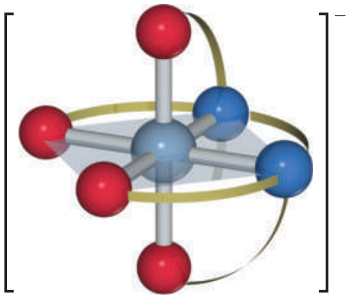
$[Co(en)_3]^{3+}$

▶ **Figure 23.11 The $[Co(en)_3]^{3+}$ ion.** The abbreviation en is used for the bidentate ethylenediamine ligand.

$$[\mathrm{Ni(H_2O)_6}]^{2+}(aq) + 3\,\mathrm{en}(aq) \rightleftharpoons [\mathrm{Ni(en)_3}]^{2+}(aq) + 6\,\mathrm{H_2O}(l)$$

$$K_f = 6.8 \times 10^{17} \qquad [23.5]$$

Although the donor atom is nitrogen in both instances, $[\mathrm{Ni(en)_3}]^{2+}$ has a formation constant that is more than 10^8 times larger than that of $[\mathrm{Ni(NH_3)_6}]^{2+}$. This trend of generally larger formation constants for bidentate and polydentate ligands, known as the **chelate effect**, is examined in the “A Closer Look” box on “Entropy and the Chelate Effect” in this section.



▲ **Figure 23.12 The complex ion $[\mathrm{Co(EDTA)}]^-$.** The ligand is the polydentate ethylenediaminetetraacetate ion, whose unabbreviated structure is given in Table 23.2. This representation shows how the two N and four O donor atoms coordinate to cobalt.

Chelating agents are often used to prevent one or more of the customary reactions of a metal ion without removing the ion from solution. For example, a metal ion that interferes with a chemical analysis can often be complexed and its interference thereby removed. In a sense, the chelating agent hides the metal ion. For this reason, scientists sometimes refer to these ligands as *sequestering agents*. Phosphate ligands, such as sodium tripolyphosphate, $\mathrm{Na_5[OPO_2OPO_2OPO_3]}$, are used to sequester $\mathrm{Ca^{2+}}$ and $\mathrm{Mg^{2+}}$ ions in hard water so that these ions cannot interfere with the action of soap or detergents.

Chelating agents are used in many prepared foods, such as salad dressings and frozen desserts, to complex trace metal ions that catalyze decomposition reactions. Chelating agents are used in medicine to remove toxic heavy metal ions that have been ingested, such as $\mathrm{Hg^{2+}}$, $\mathrm{Pb^{2+}}$, and $\mathrm{Cd^{2+}}$. One method of treating lead poisoning, for example, is to administer $\mathrm{Na_2Ca(EDTA)}$. The EDTA chelates the lead, allowing it to be removed from the body via urine.

Metals and Chelates in Living Systems

Ten of the 29 elements known to be essential for human life are transition metals [see the “Chemistry and Life” box on “Elements Required by Living Organisms” (Section 2.7)]. These 10 elements—V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Mo, and Cd—form complexes with a variety of groups present in biological systems.

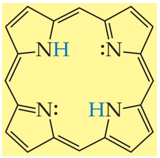
Although our bodies require only small quantities of metals, deficiencies can lead to serious illness. Iron deficiency, for example, can lead to *anemia*, in which the body lacks an adequate supply of healthy red blood cells, as is discussed in the “Chemistry and Life” box on “The Battle for Iron in Living Systems” in this section. A deficiency of manganese can lead to convulsive disorders. Some epilepsy patients have been helped by the addition of manganese to their diets.

Among the most important chelating agents in nature are those derived from the *porphine* molecule (**Figure 23.13**). This molecule can coordinate to a metal via its four nitrogen donor atoms. Once porphine bonds to a metal ion, the two H atoms on the nitrogens are displaced to form complexes called **porphyrins**. Two important porphyrins are *hemes*, in which the metal ion is Fe(II), and *chlorophylls*, with a Mg(II) central ion.

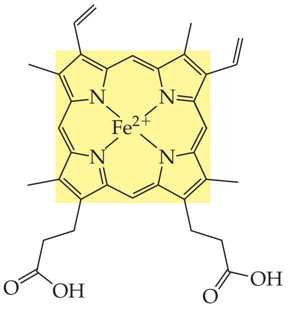
Figure 23.14 shows a schematic structure of myoglobin, a protein that contains one heme group. Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Myoglobin is found in the cells of skeletal muscle, particularly in seals, whales, and porpoises. It stores oxygen in cells, one molecule of $\mathrm{O_2}$ per myoglobin, until it is needed for metabolic activities. Hemoglobin, the protein that transports oxygen in human blood, is made up of four heme-containing subunits, each of which is very similar to myoglobin. One hemoglobin can bind up to four $\mathrm{O_2}$ molecules.

Go Figure

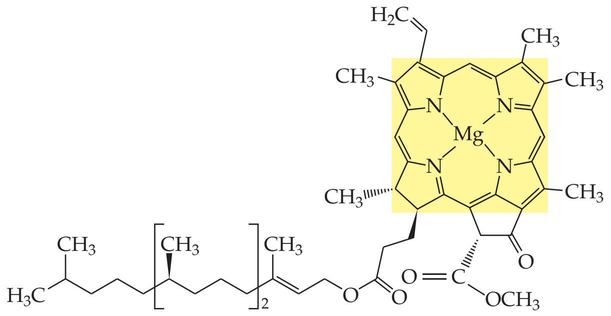
How many carbon atoms are there in porphine? How many have sp^3 hybridization? How many have sp^2 hybridization?



Porphine

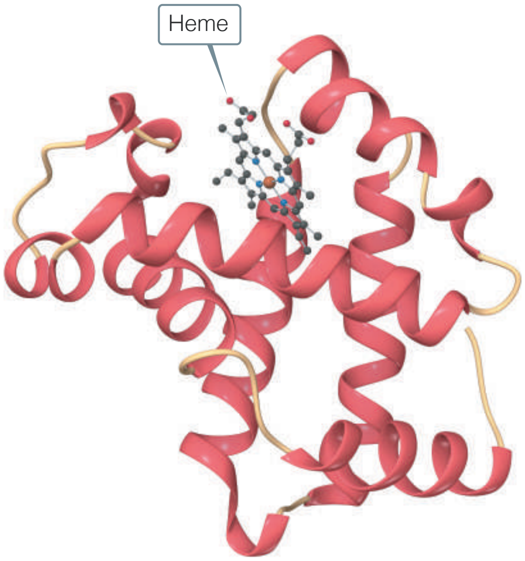


Heme b



Chlorophyll a

▲ **Figure 23.13 Porphine and two porphyrins, heme b and chlorophyll a.** Fe(II) and Mg(II) ions replace the two blue H atoms in porphine and bond with all four nitrogens in heme b and chlorophyll a, respectively.



▲ **Figure 23.14 Myoglobin.** This ribbon diagram does not show most of the atoms.

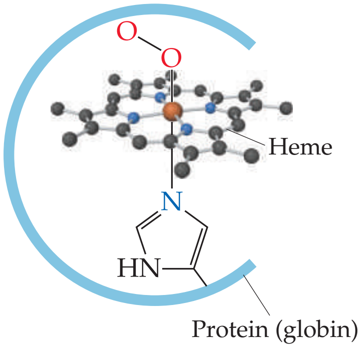
In both myoglobin and hemoglobin, the iron is coordinated to the four nitrogen atoms of a porphyrin and to a nitrogen atom from the protein chain (**Figure 23.15**). In hemoglobin, the sixth position around the iron is occupied either by O_2 (in oxyhemoglobin, the bright red form) or by water (in deoxyhemoglobin, the purplish red form). The oxy form is the one shown in Figure 23.15.

Carbon monoxide is poisonous because the equilibrium binding constant of human hemoglobin for CO is about 210 times greater than that for O_2. As a result, a relatively small quantity of CO can inactivate a substantial fraction of the hemoglobin in the blood by displacing the O_2 molecule from the heme-containing subunit. For example, a person breathing air that contains only 0.1% CO takes in enough CO after a few hours to convert up to 60% of the hemoglobin (Hb) into COHb, thereby reducing the blood's normal oxygen-carrying capacity by 60%.

Under normal conditions, a nonsmoker breathing unpolluted air has about 0.3 to 0.5% COHb in their blood. This amount arises mainly from the production of small quantities of CO in the course of normal body chemistry and from the small amount of CO present in clean air. Exposure to higher concentrations of CO causes the COHb level to increase, which in turn leaves fewer Hb sites to which O_2 can bind. If the level of COHb becomes too high, oxygen transport is effectively shut down and death occurs. Because CO is colorless and odorless, CO poisoning occurs with very little warning. Improperly ventilated combustion devices, such as kerosene lanterns and stoves, thus pose a potential health hazard.

Go Figure

What is the coordination number of iron in the heme unit shown here? What is the identity of the blue donor atoms in the heme?



▲ **Figure 23.15 Coordination sphere of the hemes in oxymyoglobin and oxyhemoglobin.**

A CLOSER LOOK Entropy and the Chelate Effect

In our discussion of Gibbs free energy, we learned that chemical processes are favored by positive entropy changes and by negative enthalpy changes. (Section 19.5) The special stability associated with the formation of chelates, called the *chelate effect*, can be explained by comparing the entropy changes that occur with monodentate ligands with the entropy changes that occur with polydentate ligands.

We begin with the reaction in which two H_2O ligands of the square-planar Cu(II) complex $[Cu(H_2O)_4]^{2+}$ are replaced by monodentate NH_3 ligands at 27 °C:

$$[Cu(H_2O)_4]^{2+}(aq) + 2\,NH_3(aq) \rightleftharpoons [Cu(H_2O)_2(NH_3)_2]^{2+}(aq) + 2\,H_2O(l)$$

$$\Delta H^\circ = -46\text{ kJ};\quad \Delta S^\circ = -8.4\text{ J/K};\quad \Delta G^\circ = -43\text{ kJ}$$

The thermodynamic data tell us about the relative abilities of H_2O and NH_3 to serve as ligands in this reaction. In general, NH_3 binds more tightly to metal ions than does H_2O, so this substitution reaction is exothermic ($\Delta H < 0$). The stronger bonding of the NH_3 ligands also causes the $[Cu(H_2O)_2(NH_3)_2]^{2+}$ ion to be more rigid, which is probably the reason ΔS° is slightly negative.

We can use Equation 19.20, $\Delta G^\circ = -RT\ln K$, to calculate the equilibrium constant of the reaction at 27 °C. The result, $K = 3.1 \times 10^7$, tells us that the equilibrium lies far to the right, favoring replacement of H_2O by NH_3. For this equilibrium, therefore, the enthalpy change, $\Delta H^\circ = -46$ kJ, is large enough and negative enough to overcome the entropy change, $\Delta S^\circ = -8.4$ J/K.

Now let's use a single bidentate ethylenediamine (en) ligand in our substitution reaction:

$$[Cu(H_2O)_4]^{2+}(aq) + en(aq) \rightleftharpoons [Cu(H_2O)_2(en)]^{2+}(aq) + 2\,H_2O(l)$$

$$\Delta H^\circ = -54\text{ kJ};\quad \Delta S^\circ = +23\text{ J/K};\quad \Delta G^\circ = -61\text{ kJ}$$

The en ligand binds slightly more strongly to the Cu^{2+} ion than two NH_3 ligands, so the enthalpy change here (−54 kJ) is slightly more negative than for $[Cu(H_2O)_2(NH_3)_2]^{2+}$(−46 kJ). There is a big difference in the entropy change, however: ΔS° is −8.4 J/K for the NH_3 reaction but +23 J/K for the en reaction. We can explain the positive ΔS° value using concepts discussed in Section 19.3. Because a single en ligand occupies two coordination sites, two molecules of H_2O are released when one en ligand bonds. Thus, there are three product molecules in the reaction but only two reactant molecules. The greater number of product molecules leads to the positive entropy change for the equilibrium.

The slightly more negative value of ΔH° for the en reaction (−54 kJ versus −46 kJ) coupled with the positive entropy change leads to a much more negative value of ΔG° (−61 kJ for en, −43 kJ for NH_3) and thus a larger equilibrium constant: $K = 4.2 \times 10^{10}$.

We can combine our two equations using Hess's law (Section 5.6) to calculate the enthalpy, entropy, and free-energy changes that occur for en to replace ammonia as ligands on Cu(II):

$$[Cu(H_2O)_2(NH_3)_2]^{2+}(aq) + en(aq) \rightleftharpoons [Cu(H_2O)_2(en)]^{2+}(aq) + 2\,NH_3(aq)$$

$$\Delta H^\circ = (-54\text{ kJ}) - (-46\text{ kJ}) = -8\text{ kJ}$$

$$\Delta S^\circ = (+23\text{ J/K}) - (-8.4\text{ J/K}) = +31\text{ J/K}$$

$$\Delta G^\circ = (-61\text{ kJ}) - (-43\text{ kJ}) = -18\text{ kJ}$$

Notice that at 27 °C, the entropic contribution ($-T\Delta S^\circ$) to the free-energy change, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ (Equation 19.12), is negative and greater in magnitude than the enthalpic contribution (ΔH°). The equilibrium constant for the substitution of two NH_3 ligands by one en ligand, 1.4×10^3, shows that the replacement of NH_3 by en is thermodynamically favorable.

The chelate effect is important in biochemistry and molecular biology. The additional thermodynamic stabilization provided by entropy effects helps stabilize biological metal–chelate complexes, such as porphyrins, and can allow changes in the oxidation state of the metal ion while retaining the structural integrity of the complex.

Related Exercise: 23.32

The **chlorophylls**, which are porphyrins that contain Mg(II) (Figure 23.13), are the key components in the conversion of solar energy into forms that can be used by living organisms. This process, called **photosynthesis**, occurs in the leaves of green plants:

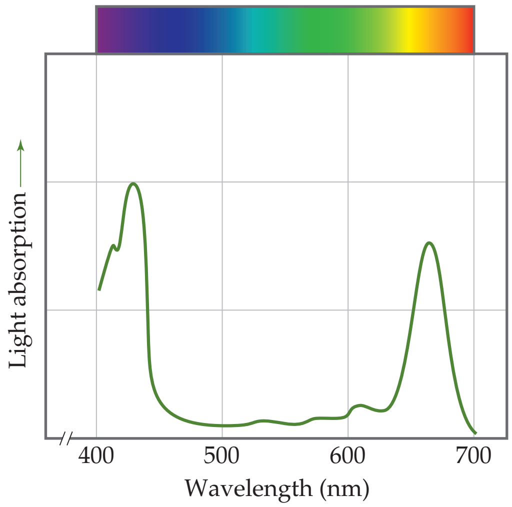
$$6\,CO_2(g) + 6\,H_2O(l) \longrightarrow C_6H_{12}O_6(aq) + 6\,O_2(g) \qquad [23.6]$$

The formation of 1 mol of glucose, $C_6H_{12}O_6$, requires the absorption of 48 mol of photons from sunlight or other sources of light. Chlorophyll-containing pigments in the leaves of plants absorb the photons. Figure 23.13 shows that the chlorophyll molecule has a series of alternating, or *conjugated*, double bonds in the ring surrounding the metal ion. This system of conjugated double bonds makes it possible for chlorophyll to absorb light strongly in the visible region of the spectrum. As **Figure 23.16** shows, chlorophyll is green because it absorbs red light (maximum absorption at 655 nm) and blue light (maximum absorption at 430 nm) and transmits green light.

Photosynthesis is nature's solar energy-conversion machine, and thus the sustainability of all living systems on Earth depends on photosynthesis. The form of chlorophyll that facilitates photosynthesis, called *chlorophyll a*, is illustrated in Figure 23.13 and on the front cover of this book.

Go Figure

Which peak in this curve corresponds to the lowest-energy transition by an electron in a chlorophyll molecule?

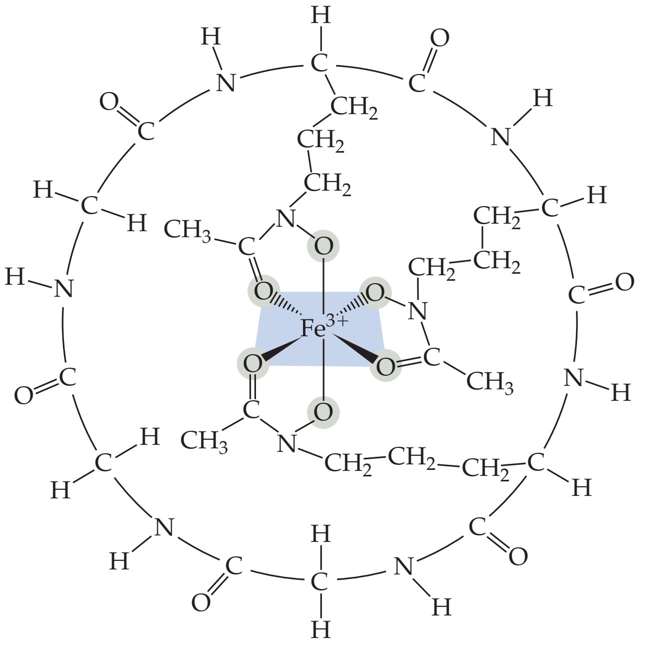


▲ **Figure 23.16 The absorption of sunlight by chlorophyll.**

CHEMISTRY AND LIFE The Battle for Iron in Living Systems

Because living systems have difficulty assimilating enough iron to satisfy their nutritional needs, iron-deficiency anemia is a common problem in humans. Chlorosis, an iron deficiency in plants that makes leaves turn yellow, is also commonplace.

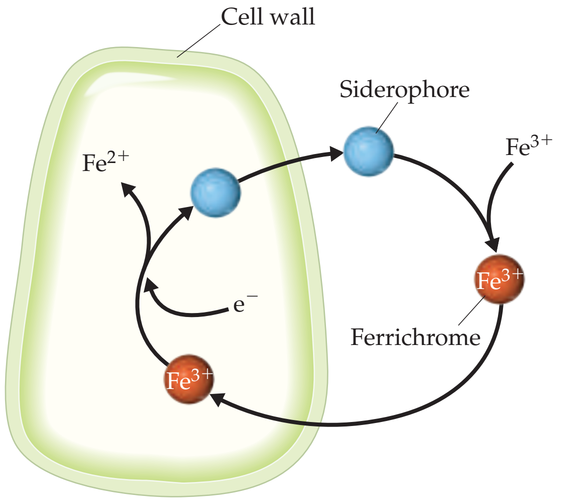
Living systems have difficulty assimilating iron because most iron compounds found in nature are not very soluble in water. Microorganisms have adapted to this problem by secreting an iron-binding compound, called a *siderophore*, that forms an extremely stable water-soluble complex with iron(III). One such complex is *ferrichrome* (**Figure 23.17**). The iron-binding strength of a siderophore is so great that it can extract iron from iron oxides.



▲ **Figure 23.17** **Ferrichrome.**

When ferrichrome enters a living cell, the iron it carries is removed through an enzyme-catalyzed reaction that reduces the strongly bonding iron(III) to iron(II), which is only weakly complexed by the siderophore (**Figure 23.18**). Microorganisms thus acquire iron by excreting a siderophore into their immediate environment and then taking the resulting iron complex into the cell.

In humans, iron is assimilated from food in the intestine. A protein called *transferrin* binds iron and transports it across the intestinal wall to distribute it to other tissues in the body. The normal adult body contains about 4 g of iron. At any one time, about 3 g of this iron is in the blood, mostly in the form of hemoglobin. Most of the remainder is carried by transferrin.



▲ **Figure 23.18** **The iron-transport system of a bacterial cell.**

A bacterium that infects the blood requires a source of iron if it is to grow and reproduce. The bacterium excretes a siderophore into the blood to compete with transferrin for iron. The equilibrium constants for forming the iron complex are about the same for transferrin and siderophores. The more iron available to the bacterium, the more rapidly it can reproduce and thus the more harm it can do.

Several years ago, New Zealand clinics regularly gave iron supplements to infants soon after birth. However, the incidence of certain bacterial infections was eight times higher in treated than in untreated infants. Presumably, the presence of more iron in the blood than is absolutely necessary makes it easier for bacteria to obtain the iron needed for growth and reproduction.

In the United States, it is common medical practice to supplement infant formula with iron sometime during the first year of life. However, iron supplements are not necessary for infants who breastfeed because breast milk contains two specialized proteins, lactoferrin and transferrin, which provide sufficient iron while denying its availability to bacteria. Even for infants fed with infant formulas, supplementing with iron during the first several months of life may be ill-advised.

For bacteria to continue to multiply in the blood, they must synthesize new supplies of siderophores. Synthesis of siderophores in bacteria slows, however, as the temperature is increased above the normal body temperature of 37 °C and stops completely at 40 °C. This suggests that fever in the presence of an invading microbe is a mechanism used by the body to deprive bacteria of iron.

Self-Assessment Exercises

SAE 23.8 The oxalate ion, $C_2O_4^{2-}$, denoted *ox*, forms a complex ion with chromium: $[Cr(ox)_3]^{3-}$. Which of the following statements about this complex is *false*?

(**a**) The oxalate ion is a bidentate ligand.
(**b**) The coordination number for this complex is 3.
(**c**) The oxidation state of chromium in this complex is +3.
(**d**) The donor atoms in the ox ligand are oxygen atoms.
(**e**) The oxalate ion is an example of a chelating ligand.

SAE 23.9 *Chlorophyll a* is a porphyrin complex that is the principal substance involved in photosynthesis by plants. Which of the following statements about chlorophyll a is *true*?

(**a**) Chlorophyll a is an example of a transition-metal complex.
(**b**) The porphyrin is a bidentate ligand.
(**c**) Chlorophyll a can absorb visible light.
(**d**) The metal atom in chlorophyll a is in the +3 oxidation state.
(**e**) The metal atom at the center of chlorophyll a is manganese.

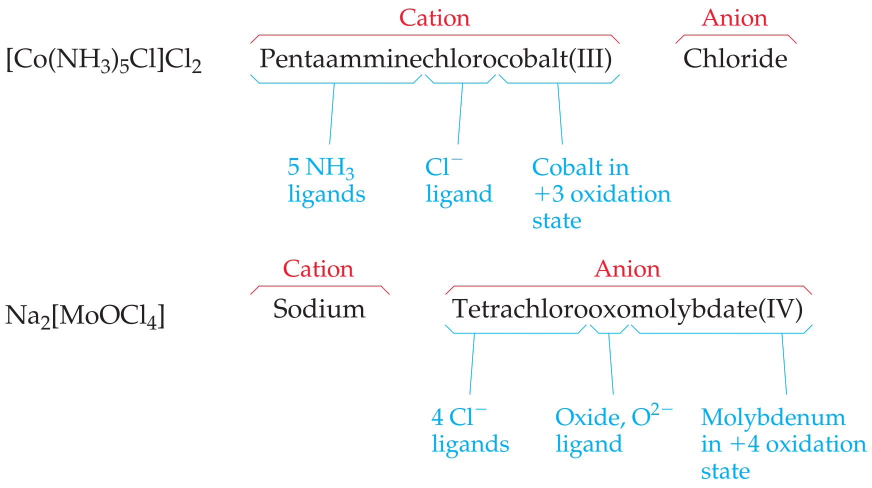
23.4 Nomenclature and Isomerism in Coordination Chemistry

When complexes were first discovered, they were named after the chemist who originally prepared them. A few of these names persist; for example, the dark red substance $NH_4[Cr(NH_3)_2(NCS)_4]$ is still known as Reinecke's salt. Once the structures of complexes were more fully understood, it became possible to name them in a more systematic manner. Let's use two substances to illustrate how coordination compounds are named:

Learning Objectives

When you finish Section 23.4, you should be able to:

- Convert between the name of a coordination compound and its chemical formula.
- Describe the types of isomerization a coordination complex can exhibit.
- Describe how optical isomers of a complex differ from one another.



How to Name Coordination Compounds

1. *In naming complexes that are salts, the name of the cation is given before the name of the anion*. Thus, in $[Co(NH_3)_5Cl]Cl_2$ we name the $[Co(NH_3)_5Cl]^{2+}$ cation and then the Cl^-.
2. *In naming complex ions or molecules, the ligands are named before the metal. Ligands are listed in alphabetical order, regardless of their charges. Prefixes that give the number of ligands are not considered part of the ligand name in determining alphabetical order*. Thus, the $[Co(NH_3)_5Cl]^{2+}$ ion is pentaamminechlorocobalt(III). (Be careful to note, however, that the metal is written first in the chemical formula.)
3. *The names of anionic ligands end in the letter o, but electrically neutral ligands ordinarily bear the name of the molecules* (Table 23.5). Special names are used for H_2O (aqua), NH_3 (ammine), and CO (carbonyl). For example, $[Fe(CN)_2(NH_3)_2(H_2O)_2]^+$ is the diamminediaquadicyanoiron(III) ion.
4. *Greek prefixes* (di-, tri-, tetra-, penta-, hexa-*) are used to indicate the number of each kind of ligand when more than one is present. If the ligand contains a Greek prefix (for example, ethylenediamine) or is polydentate, the alternate prefixes* bis-, tris-, tetrakis-, pentakis-, *and* hexakis- *are used and the ligand name is placed in parentheses*. For example, the name for $[Co(en)_3]Br_3$ is tris(ethylenediamine)cobalt(III) bromide.
5. *If the complex is an anion, its name ends in* -ate. The compound $K_4[Fe(CN)_6]$ is potassium hexacyanoferrate(II), for example, and the ion $[CoCl_4]^{2-}$ is tetrachlorocobaltate(II) ion.
6. *The oxidation state of the metal is given in parentheses in Roman numerals following the name of the metal*. There is no space between the name of the metal and the parenthesis.

   Three examples for applying these rules are

$[Ni(NH_3)_6]Br_2$	Hexaamminenickel(II) bromide
$[Co(en)_2(H_2O)(CN)]Cl_2$	Aquacyanobis(ethylenediamine)cobalt(III) chloride
$Na_2[MoOCl_4]$	Sodium tetrachlorooxomolybdate(IV)

TABLE 23.5 Some Common Ligands and Their Names

Ligand	Name in Complexes	Ligand	Name in Complexes
Azide, N_3^-	Azido	Oxalate, $C_2O_4^{2-}$	Oxalato
Bromide, Br^-	Bromo	Oxide, O^{2-}	Oxo
Chloride, Cl^-	Chloro	Ammonia, NH_3	Ammine
Cyanide, CN^-	Cyano	Carbon monoxide, CO	Carbonyl
Fluoride, F^-	Fluoro	Ethylenediamine, en	Ethylenediamine
Hydroxide, OH^-	Hydroxo	Pyridine, C_5H_5N	Pyridine
Carbonate, CO_3^{2-}	Carbonato	Water, H_2O	Aqua

Sample Exercise 23.3

Naming Coordination Compounds

Name the compounds (**a**) $[Cr(H_2O)_4Cl_2]Cl$, (**b**) $K_4[Ni(CN)_4]$.

SOLUTION

Analyze We are given the chemical formulas for two coordination compounds and assigned the task of naming them.

Plan To name the complexes, we need to determine the ligands in the complexes, the names of the ligands, and the oxidation state of the metal ion. We then put the information together following the rules listed in the text.

Solve

(**a**) The ligands are four water molecules—tetraaqua—and two chloride ions—dichloro. By assigning all the oxidation states we know for this molecule, we see that the oxidation state of Cr is +3:

$$+3 + 4(0) + 2(-1) + (-1) = 0$$
$$\searrow \quad \searrow \quad \downarrow \quad \swarrow$$
$$[Cr(H_2O)_4Cl_2]Cl$$

Thus, we have chromium(III). Finally, the anion is chloride. The name of the compound is tetraaquadichlorochromium(III) chloride.

(**b**) The complex has four cyanide ion ligands, CN^-, which means tetracyano, and the oxidation state of the nickel is zero:

$$4(+1) + 0 + 4(-1) = 0$$
$$\downarrow \quad \swarrow \quad \swarrow$$
$$K_4[Ni(CN)_4]$$

Because the complex is an anion, the metal is indicated as nickelate(0). Putting these parts together and naming the cation first, we have potassium tetracyanonickelate(0).

Practice Exercise

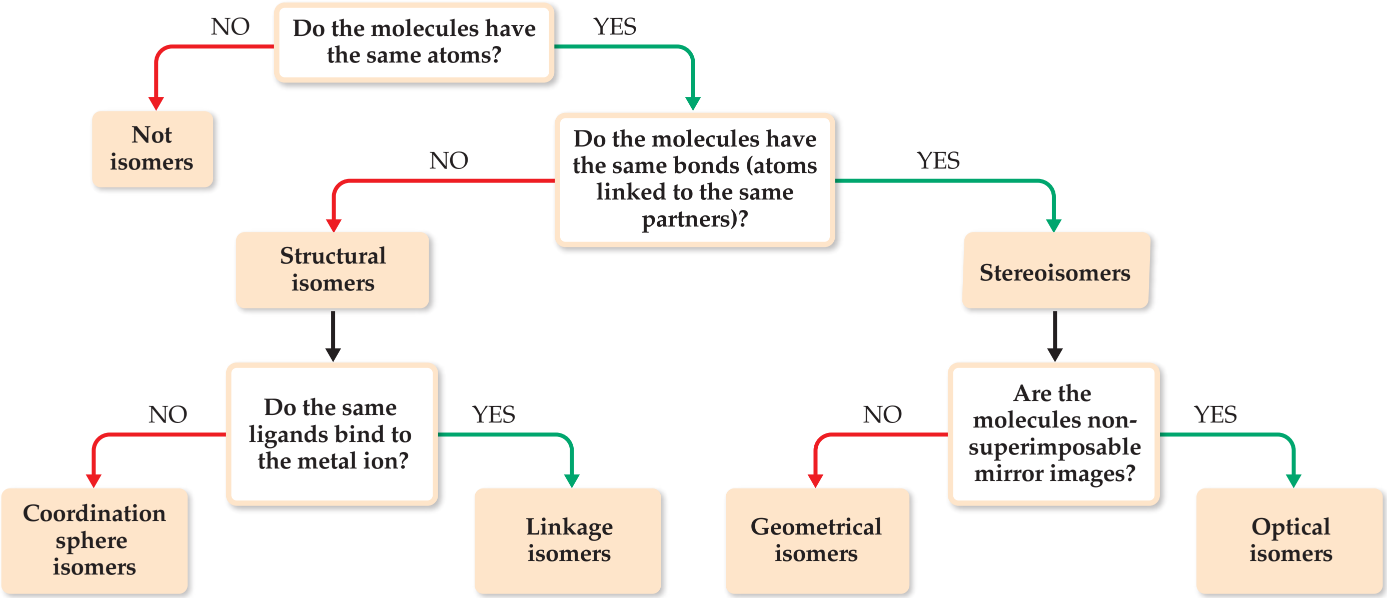
Write names for the compounds (**a**) $[Mo(NH_3)_3Br_3]NO_3$, (**b**) $(NH_4)_2[CuBr_4]$. (**c**) Write the formula for sodium diaquabis(oxalato)ruthenate(III).

Isomerism

When two or more compounds have the same composition but a different arrangement of atoms, we call them **isomers**. (Section 2.9) Here we consider two main kinds of isomers in coordination compounds: **structural isomers** (which have different bonds) and **stereoisomers** (which have the same bonds but different ways in which the ligands occupy the space around the metal center). Each of these classes also has subclasses, as shown in **Figure 23.19**.

Structural Isomerism

Many types of structural isomerism are known in coordination chemistry, including the two named in Figure 23.19: linkage isomerism and coordination-sphere isomerism. **Linkage isomerism** is a relatively rare but interesting type that arises when a particular ligand is capable of coordinating to a metal in two ways. The nitrite ion, NO_2^-, for example, can coordinate to a metal ion through either its nitrogen or one of its oxygens (**Figure 23.20**). When it coordinates through the nitrogen atom, the NO_2^- ligand is called *nitro*; when it coordinates through the oxygen atom, it is called *nitrito* and is generally written ONO^-. The isomers shown in Figure 23.20 have different properties. The nitro isomer is orange, for example, whereas the nitrito isomer is red.

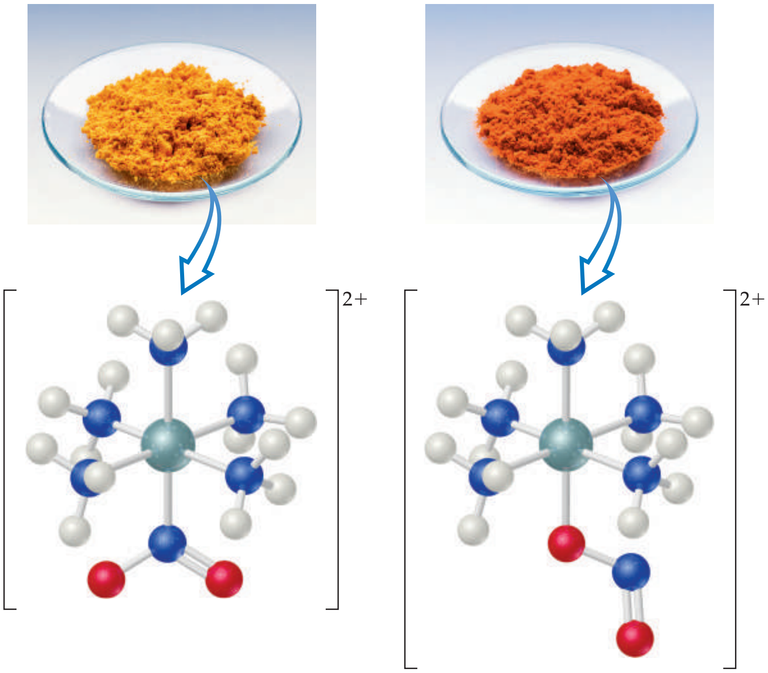


Do the molecules have the same atoms?
NO
YES
Not isomers
Do the molecules have the same bonds (atoms linked to the same partners)?
NO
YES
Structural isomers
Stereoisomers
Do the same ligands bind to the metal ion?
NO
YES
Coordination sphere isomers
Linkage isomers
Are the molecules non-superimposable mirror images?
NO
YES
Geometrical isomers
Optical isomers

▲ **Figure 23.19** **Forms of isomerism in coordination compounds.**

Go Figure

What are the chemical formula and name for each of the complex ions in this figure?



Nitro isomer
Bonding via ligand N atom

Nitrito isomer
Bonding via ligand O atom

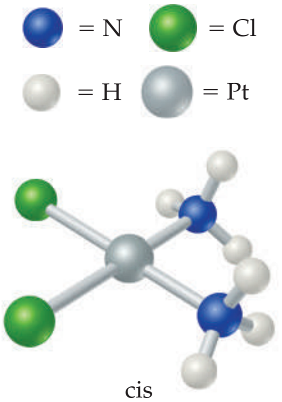
▲ **Figure 23.20** **Linkage isomerism.** The orange N-bound isomer (left) and the red O-bound isomer (right) of $[Co(NH_3)_5NO_2]^{2+}$.

Another ligand capable of coordinating through either of two donor atoms is thiocyanate, SCN^-, whose potential donor atoms are N and S.

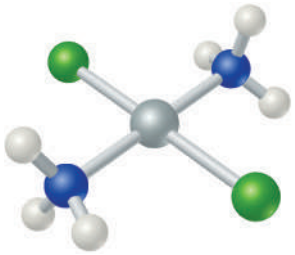
Coordination-sphere isomers differ in which species in the complex act as ligands and which are outside the coordination sphere. For example, three isomers have the formula $CrCl_3(H_2O)_6$. When the ligands are six H_2O and the chloride ions are in the crystal lattice (as counterions), we have the violet compound $[Cr(H_2O)_6]Cl_3$. When the ligands are five H_2O and one Cl^-, with the sixth H_2O and the two additional Cl^- ions out in the lattice, we have the green compound $[Cr(H_2O)_5Cl]Cl_2 \cdot H_2O$. The third isomer, $[Cr(H_2O)_4Cl_2]Cl \cdot 2\ H_2O$, is also a green compound. In the two green compounds, either one or two water molecules have been displaced from the coordination sphere by chloride ions. The displaced H_2O molecules occupy a site in the crystal lattice.

Go Figure

Which of these isomers has a nonzero dipole moment?



cis
Cl ligands adjacent to each other
NH_3 ligands adjacent to each other



trans
Cl ligands on opposite sides of central atom
NH_3 ligands on opposite sides of central atom

▲ **Figure 23.21** **Geometric isomerism.**

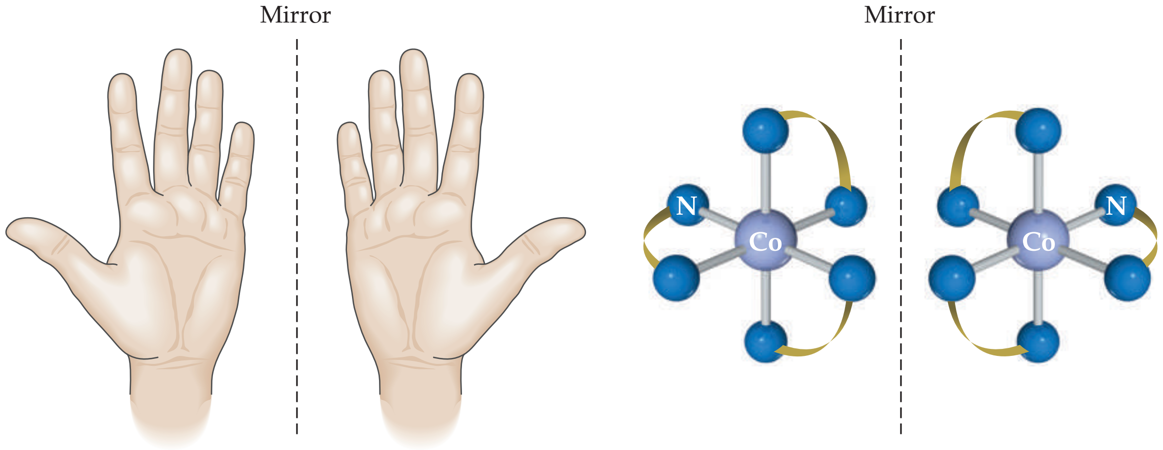
Stereoisomerism

Stereoisomers have the same chemical bonds but different spatial arrangements. In the square-planar complex $[Pt(NH_3)_2Cl_2]$, for example, the chloro ligands can be either adjacent to or opposite each other (**Figure 23.21**). (We saw an earlier example of this type of isomerism in the cobalt complex of Figure 23.8, and we will return to that complex in a moment.) This form of stereoisomerism, in which the arrangement of the atoms is different but the same bonds are present, is called **geometric isomerism**. The isomer with like ligands in adjacent positions is the cis isomer, and the isomer with like ligands across from one another is the trans isomer.

Geometric isomers generally have different physical properties and may also have markedly different chemical reactivities. For example, *cis*-$[Pt(NH_3)_2Cl_2]$, also called *cisplatin*, is effective in the treatment of testicular, ovarian, and certain other cancers, whereas the trans isomer is ineffective. This is because cisplatin forms a chelate with two nitrogens of DNA, displacing the chloride ligands. The chloride ligands of the trans isomer are too far apart to form the N–Pt–N chelate with the nitrogen donors in DNA.

Geometric isomerism is also possible in octahedral complexes when two or more different ligands are present, as in the cis and trans tetraamminedichlorocobalt(III) ion in Figure 23.8. Because all four vertices of a tetrahedron are adjacent to one another, cis–trans isomerism is not observed in tetrahedral complexes.

The second type of stereoisomerism listed in Figure 23.19 is **optical isomerism**. Optical isomers, called **enantiomers**, are mirror images that cannot be superimposed on each other. They bear the same resemblance to each other that your left hand bears to your right hand. If you look at your left hand in a mirror, the image is identical to your right hand (**Figure 23.22**). No matter how hard you try, however, you cannot superimpose your two hands on each other. An example of a complex that exhibits this type of isomerism is the $[Co(en)_3]^{3+}$ ion. Figure 23.22 shows the two enantiomers of this complex and their mirror-image relationship. Just as there is no way that we can twist or turn our right hand to make it look identical to our left, so also there is no way to rotate one of these enantiomers to make it identical to the other. Molecules or ions that are not superimposable on their mirror image are said to be **chiral** (pronounced KY-rul).

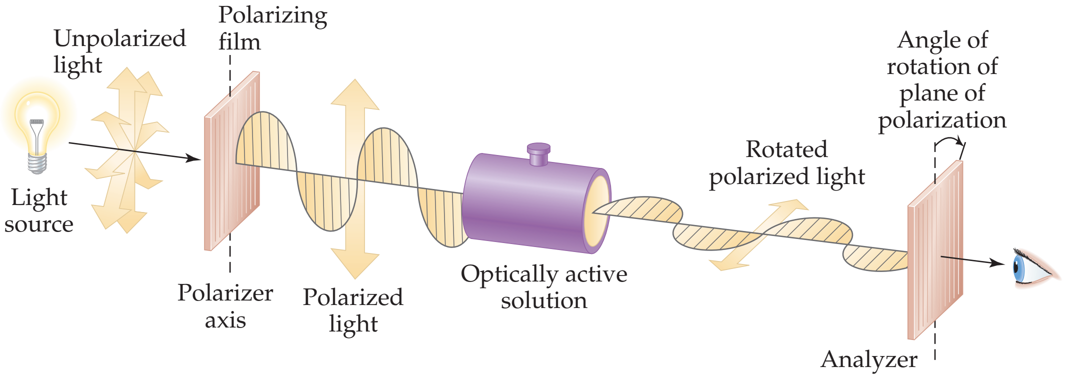


Left hand

Mirror image of left hand is identical to right hand

Enantiomers of $[Co(en)_3]^{3+}$

▲ **Figure 23.22** **Optical isomerism.**



▲ **Figure 23.23** **Using polarized light to detect optical activity.**

The properties of two optical isomers differ only if the isomers are in a chiral environment—that is, an environment in which there is a sense of right- and left-handedness. A chiral enzyme, for example, might catalyze the reaction of one optical isomer but not the other. Consequently, one optical isomer may produce a specific physiological effect in the body, with its mirror image producing either a different effect or none at all. Chiral reactions are also extremely important in the synthesis of pharmaceuticals and other industrially important chemicals.

Optical isomers are usually distinguished from each other by their interaction with plane-polarized light. If light is polarized—for example, by being passed through a sheet of polarizing film—the electric-field vector of the light is confined to a single plane (**Figure 23.23**). If the polarized light is then passed through a solution containing one optical isomer, the plane of polarization is rotated either to the right or to the left. The isomer that rotates the plane of polarization to the right is **dextrorotatory**; it is the dextro, or *d*, isomer (Latin *dexter*, "right"). Its mirror image rotates the plane of polarization to the left; it is **levorotatory** and is the levo, or *l*, isomer (Latin *laevus*, "left"). The $[\mathrm{Co(en)_3}]^{3+}$ isomer on the right in Figure 23.22 is found experimentally to be the *l* isomer of this ion. Its mirror image is the *d* isomer. Because of their effect on plane-polarized light, chiral molecules are said to be **optically active**.

Sample Exercise 23.4

Determining the Number of Geometric Isomers

The Lewis structure :C≡O: indicates that the CO molecule has two lone pairs of electrons. When CO binds to a transition-metal atom, it nearly always does so by using the C lone pair. How many geometric isomers are there for tetracarbonyldichloroiron(II)?

SOLUTION

Analyze We are given the name of a complex containing only monodentate ligands, and we must determine the number of isomers the complex can form.

Plan We can count the number of ligands to determine the coordination number of the Fe and then use the coordination number to predict the geometry. We can then either make a series of drawings with ligands in different positions to determine the number of isomers or deduce the number of isomers by analogy to cases we have discussed.

Solve The name indicates that the complex has four carbonyl (CO) ligands and two chloro ($\mathrm{Cl^-}$) ligands, so its formula is $\mathrm{Fe(CO)_4Cl_2}$. The complex therefore has a coordination number of 6, and we can assume an octahedral geometry. Like $[\mathrm{Co(NH_3)_4Cl_2}]^+$ (Figure 23.8), it has four ligands of one type and two of another. Consequently, there are two isomers possible: one with the $\mathrm{Cl^-}$ ligands across the metal from each other (that is, separated by 180°), *trans*-$[\mathrm{Fe(CO)_4Cl_2}]$, and one with the $\mathrm{Cl^-}$ ligands adjacent to each other (that is, separated by 90°), *cis*-$[\mathrm{Fe(CO)_4Cl_2}]$.

Comment It is easy to overestimate the number of geometric isomers. Sometimes different orientations of a single isomer are incorrectly thought to be different isomers. If two structures can be rotated so that they are equivalent, they are not isomers of each other. The problem of identifying isomers is compounded by the difficulty we often have in visualizing three-dimensional molecules from their two-dimensional representations. It is sometimes easier to determine the number of isomers if we use three-dimensional models.

▶ Practice Exercise

How many isomers exist for the square-planar molecule $[\mathrm{Pt(NH_3)_2ClBr}]$?

Sample Exercise 23.5

Predicting Whether a Complex Has Optical Isomers

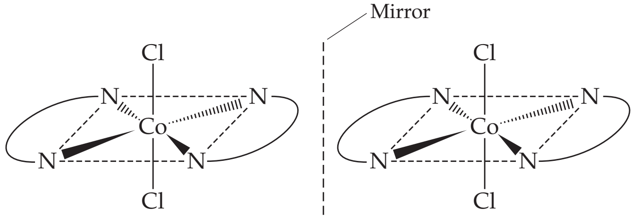
Does either *cis*-$[Co(en)_2Cl_2]^+$ or *trans*-$[Co(en)_2Cl_2]^-$ have optical isomers?

SOLUTION

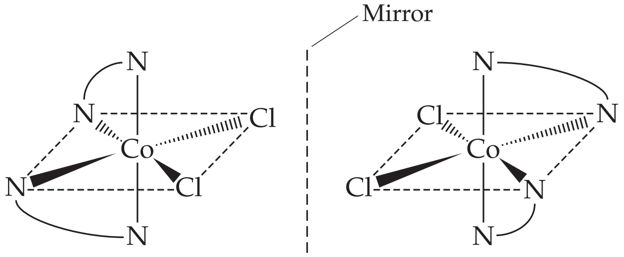
Analyze We are given the chemical formula for two geometric isomers and asked to determine whether either one has optical isomers. Because en is a bidentate ligand, we know that both complexes are octahedral and both have coordination number 6.

Plan We need to sketch the structures of the cis and trans isomers and their mirror images. We can draw the en ligand as two N atoms connected by an arc. If the mirror image cannot be superimposed on the original structure, the complex and its mirror image are optical isomers.

Solve The trans isomer of $[Co(en)_2Cl_2]^+$ and its mirror image are shown here. Notice that the mirror image of the isomer is identical to the original. Consequently *trans*-$[Co(en)_2Cl_2]^+$ does *not* exhibit optical isomerism.



The cis isomer of $[Co(en)_2Cl_2]^+$ and its mirror image are shown here. In this case, the two cannot be superimposed on each other. Thus, the two cis structures are optical isomers (enantiomers). We say that *cis*-$[Co(en)_2Cl_2]^+$ is a chiral complex.



Practice Exercise

Does the square-planar complex ion $[Pt(NH_3)(N_3)ClBr]^-$ have optical isomers? Explain your answer.

When a substance with optical isomers is prepared in the laboratory, the chemical environment during the synthesis is not usually chiral. Consequently, equal amounts of the two isomers are obtained, and the mixture is said to be **racemic**. A racemic mixture does not rotate polarized light because the rotatory effects of the two isomers cancel each other.

Self-Assessment Exercises

SAE 23.10 What is the correct formula for dichlorobis(ethylenediamine)cobalt(III) chloride? **(a)** $[CoCl_3(en)]Cl$ **(b)** $[Co(en)_3]Cl_3$ **(c)** $[CoCl_3(en)_2]$ **(d)** $[CoCl_2(en)]Cl$ **(e)** $[CoCl_2(en)_2]Cl$

SAE 23.11 For which of the following are the name and formula correctly matched?

- **(i)** Potassium tetrachloroplatinate(II): $K_2[PtCl_6]$
- **(ii)** Hexaaquamanganese(I) bromide: $[Mn(H_2O)_6]Br$
- **(iii)** Triamminetrichlorochromium(III): $[Cr(NH_3)_3Cl_3]$

(a) i only **(b)** ii only **(c)** i and ii **(d)** ii and iii **(e)** i, ii, and iii

SAE 23.12 Which of the following statements about isomers in coordination compounds is or are *true*?

- **(i)** The octahedral complex $[CoCl_4F_2]^{3-}$ has two geometrical isomers.
- **(ii)** In order to form linkage isomers, a ligand must have two different donor atoms.
- **(iii)** An optical isomer rotates the plane of polarization of plane-polarized light.

(a) Only one statement is true. **(b)** Statements i and ii are true. **(c)** Statements i and iii are true. **(d)** Statements ii and iii are true. **(e)** All three statements are true.

SAE 23.13 Which of the following statements about the optical isomerism is *false*?

- **(a)** Optical isomers are nonsuperimposable mirror images of one another.
- **(b)** The two optical isomers of a chiral molecule will rotate plane-polarized light in opposite directions.
- **(c)** The number and/or type of metal–ligand bonds must be different for two optical isomers of a coordination compound.
- **(d)** A racemic mixture is one that has equal amounts of the two optical isomers of a compound.
- **(e)** Some coordination compounds do not have optical isomers.

23.5 | Color and Magnetism in Coordination Chemistry

Studies of the colors and magnetic properties of transition-metal complexes have played an important role in the development of modern models for metal–ligand bonding. We discussed the various types of magnetic behavior of the transition metals in Section 23.1, and we discussed the interaction of radiant energy with matter in Section 6.3. Let's briefly examine the significance of these two properties for transition-metal complexes before we develop a model for metal–ligand bonding.

Learning Objectives

When you finish Section 23.5, you should be able to:

- Predict the color of a coordination compound from its absorption spectrum.
- Recall that the magnetic behavior of coordination compounds will depend in part on the number of electrons on the metal atom in its particular oxidation state.

Color

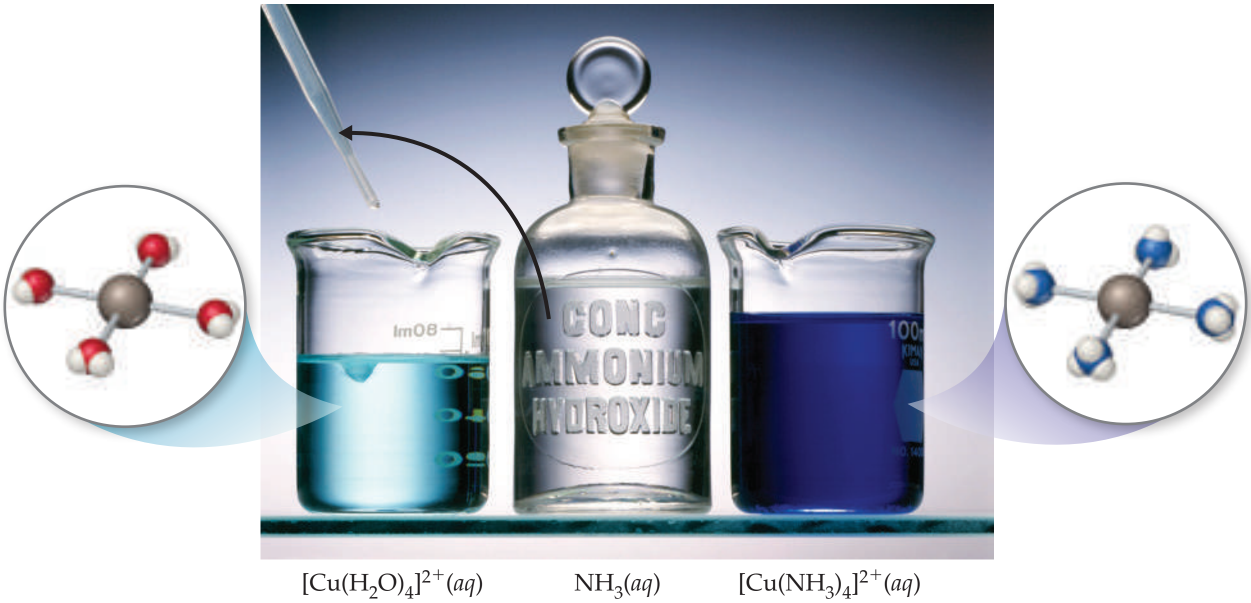
In Figure 23.4, we saw the diverse range of colors seen in salts of transition-metal ions and their aqueous solutions. In general, the color of a complex depends on the identity of the metal ion, on its oxidation state, and on the ligands bonded to it. **Figure 23.24**, for instance, shows how the pale blue color characteristic of $[Cu(H_2O)_4]^{2+}$ changes to deep blue-violet as NH_3 ligands replace the H_2O ligands to form $[Cu(NH_3)_4]^{2+}$.

For a substance to have color we can see, it must absorb some portion of the spectrum of visible light. (Section 6.1) Absorption happens, however, only if the energy needed to move an electron in the substance from its ground state to an excited state corresponds to the energy of some portion of the visible spectrum. (Section 6.3) Thus, the particular energies of radiation a substance absorbs dictate the color we see for the substance.

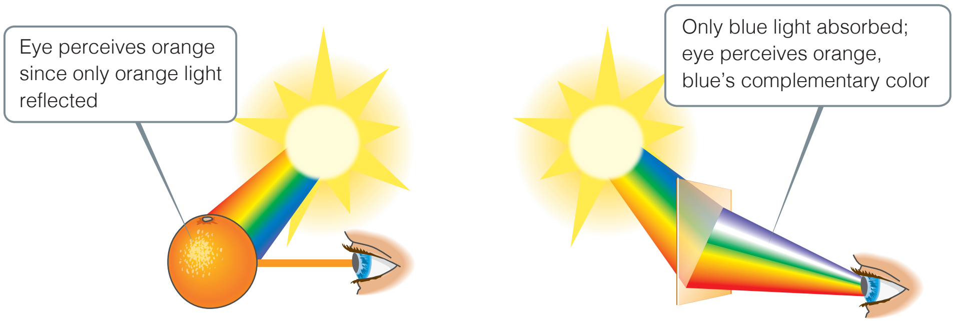
When an object absorbs some portion of the visible spectrum, the color we perceive is the sum of the unabsorbed portions, which are either reflected or transmitted by the object and strike our eyes. (Opaque objects *reflect* light, and transparent ones *transmit* it.) If an object absorbs all wavelengths of visible light, none reaches our eyes and the object

Go Figure

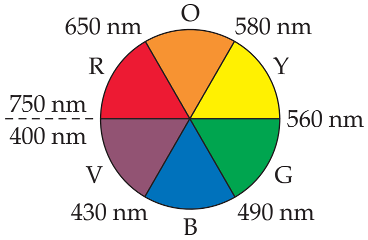
Is the equilibrium binding constant of ammonia for Cu(II) likely to be larger or smaller than that of water for Cu(II)?



▲ **Figure 23.24 The color of a coordination complex changes when the ligand changes.** When a small amount of concentrated $NH_3(aq)$ is added to a solution of $[Cu(H_2O)_4]^{2+}$, the color changes dramatically as NH_3 replaces H_2O in the coordination sphere.



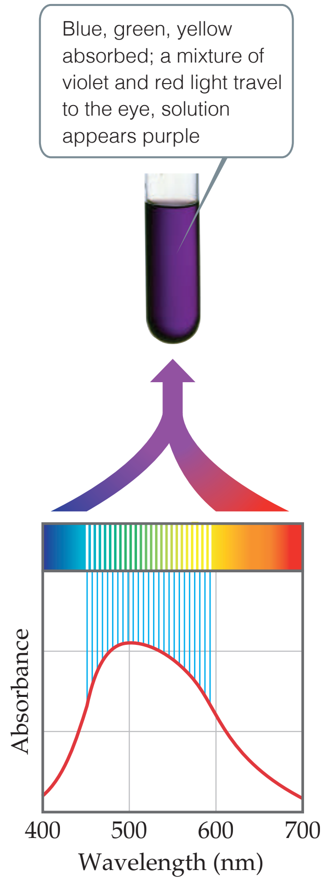
Eye perceives orange since only orange light reflected
Only blue light absorbed; eye perceives orange, blue's complementary color



▲ **Figure 23.25** **Two ways of perceiving the color orange.** An object appears orange either when it reflects orange light to the eye (left) or when it transmits to the eye all colors except blue, the complement of orange (middle). Complementary colors lie opposite to each other on an artist's color wheel (right).

Go Figure

How would this absorbance spectrum change if you decreased the concentration of the $[Ti(H_2O)_6]^{3+}$ in solution?



▲ **Figure 23.26** **The color of $[Ti(H_2O)_6]^{3+}$** A solution containing the $[Ti(H_2O)_6]^{3+}$ ion appears purple because, as its visible absorption spectrum shows, the solution does not absorb light from the violet and red ends of the spectrum. That unabsorbed light is what reaches our eyes.

appears black. If it absorbs no visible light, it is white if opaque or colorless if transparent. If it absorbs all but orange light, the orange light is what reaches our eye and therefore is the color we see.

An interesting phenomenon of vision is that we also perceive an orange color when an object absorbs only the blue portion of the visible spectrum and all the other colors strike our eyes. This is because orange and blue are **complementary colors**, which means that the removal of blue from white light makes the light look orange (and the removal of orange makes the light look blue).

Complementary colors can be determined with an artist's color wheel, which shows complementary colors on opposite sides (**Figure 23.25**). Orange and blue are complementary, as are red and green, and yellow and violet.

The amount of light absorbed by a sample as a function of wavelength is known as the sample's **absorption spectrum**. The visible absorption spectrum of a transparent sample can be determined using a spectrometer, as described in the "A Closer Look" box on "Using Spectroscopic Methods to Measure Reaction Rates: Beer's Law." (Section 14.2) The absorption spectrum of the ion $[Ti(H_2O)_6]^{3+}$ is shown in **Figure 23.26**. The absorption maximum is at 500 nm, but the graph shows that much of the yellow, green, and blue light is absorbed. Because the sample absorbs all of these colors, what we see is the unabsorbed red and violet light, which we perceive as purple (the color purple is classified as a tertiary color located between red and violet on an artist's color wheel).

Magnetism of Coordination Compounds

Many transition-metal complexes exhibit paramagnetism, as described in Sections 9.8 and 23.1. In such compounds, the metal ions possess some number of unpaired electrons. It is possible to determine experimentally the number of unpaired electrons per metal ion from the measured degree of paramagnetism, and experiments reveal some interesting comparisons.

Compounds of the complex ion $[Co(CN)_6]^{3-}$ have no unpaired electrons, for example, but compounds of the $[CoF_6]^{3-}$ ion have four unpaired electrons per metal ion. Both complexes contain Co(III) with a $3d^6$ electron configuration. (Section 7.4) As a result, there is a major difference in the ways in which the electrons are arranged in these two cases. Any successful bonding theory must explain this difference, and we present such a theory in the next section.

Sample Exercise 23.6

Relating Color Absorbed to Color Observed

The complex ion *trans*-$[Co(NH_3)_4Cl_2]^+$ absorbs light primarily in the red region of the visible spectrum (the most intense absorption is at 680 nm). What is the color of the complex ion?

SOLUTION

Analyze We need to relate the color absorbed by a complex (red) to the color observed for the complex.

Plan For an object that absorbs only one color from the visible spectrum, the color we see is complementary to the color absorbed. We can use the color wheel of Figure 23.25 to determine the complementary color.

Solve From Figure 23.25, we see that green is complementary to red, so the complex appears green.

Comment As noted in Section 23.2, this green complex helped Werner establish his theory of coordination (Table 23.3). The other geometric isomer of this complex, *cis*-$[Co(NH_3)_4Cl_2]^+$, absorbs yellow light and therefore appears violet.

▶ Practice Exercise

A certain transition-metal complex ion absorbs at 695 nm. Which color is this ion most likely to be—blue, yellow, green, or red?

Self-Assessment Exercises

SAE 23.14 The visible absorption spectrum of aqueous $[Ni(NH_3)_6]Cl_2$ has a strong absorption peak at 570 nm. What color is the solution? (**a**) blue-violet (**b**) yellow-orange (**c**) green (**d**) colorless

SAE 23.15 Which of the following statements about an aqueous solution of $[Zn(H_2O)_6]^{2+}$ is or are *true*?

(**i**) In this complex, Zn is in the +2 oxidation state.
(**ii**) In this complex, Zn has an $3d^{10}$ valence electron configuration.
(**iii**) The complex will be paramagnetic.

(**a**) Only statement i is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

23.6 | Crystal-Field Theory

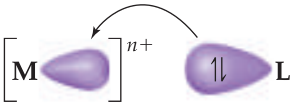
Scientists have long recognized that many of the magnetic properties and colors of transition-metal complexes are related to the presence of *d* electrons in the metal cation. In this section, we consider a model for bonding in transition-metal complexes, called **crystal-field theory**, that accounts for many of the observed properties of these substances.* Because many predictions of crystal-field theory are qualitatively the same as those obtained with more advanced molecular-orbital theories, crystal-field theory is an excellent place to start in considering the electronic structure of coordination compounds.

As we have discussed, the interaction between a ligand and a metal ion is essentially a Lewis acid–base interaction in which the base—that is, the ligand—donates a pair of electrons to an empty orbital on the metal ion (**Figure 23.27**). Much of the attractive interaction between the metal ion and the ligands is due, however, to the electrostatic forces between the positive charge on the metal ion and negative charges on the ligands. An ionic ligand, such as Cl^- or SCN^-, experiences the usual cation–anion attraction. When the ligand is a neutral molecule, as in the case of H_2O or NH_3, the negative ends of these polar molecules, which contain a lone pair, are directed toward the metal ion. In this case, the attractive interaction is of the ion–dipole type. (Section 11.2) In either case, the ligands are attracted strongly toward the metal ion. Because of the metal–ligand electrostatic attraction, the energy of the complex is lower than the combined energy of the separated metal ion and ligands.

Learning Objectives

When you finish Section 23.6, you should be able to:

- Describe the splitting of the *d* orbitals of a metal ion in an octahedral crystal field.
- Describe how visible light can lead to a *d*–*d* transition in an octahedral complex.
- Relate the ability of a ligand to increase the crystal-field splitting to the energy gap, Δ, between the t_2 and *e* sets of *d* orbitals.
- Determine the electron configurations and magnetic properties of high-spin and low-spin octahedral complexes.
- Use crystal-field theory to determine the *d*-orbital splitting patterns and number of unpaired electrons in tetrahedral and square-planar complexes.



▲ **Figure 23.27 Metal–ligand bond formation.** The ligand acts as a Lewis base by donating its lone pair to an empty orbital on the metal ion. The bond that results is strongly polar with some covalent character.

---

*The name *crystal field* arose because the theory was first developed to explain the properties of solid crystalline materials. The theory applies equally well to complexes in solution, however.

Go Figure Which *d* orbitals have lobes that point directly toward the ligands in an octahedral crystal field?

▲ **Figure 23.28 Energies of *d* orbitals in a free metal ion, a spherically symmetric crystal field, and an octahedral crystal field.** The degree of splitting of the *d* orbitals in the crystal fiend is the *crystal-field splitting energy*, denoted Δ.

Although the metal ion is attracted to the ligand electrons, the metal ion's *d* electrons are electrostatically repelled by the electrons on the ligands. Let's examine this effect more closely, specifically the case in which the ligands form an octahedral array around a metal ion that has coordination number 6.

In crystal-field theory, we consider the ligands to be negative points of charge that repel the negatively charged electrons in the *d* orbitals of the metal ion. The energy-level diagram in **Figure 23.28** shows how these ligand point charges affect the energies of the *d* orbitals. First, we imagine the complex as having all the ligand point charges uniformly distributed on the surface of a sphere centered on the metal ion. The *average* energy of the metal ion's *d* orbitals is raised by the presence of this uniformly charged sphere. Hence, the energies of all five *d* orbitals are raised by the same amount—the *d* orbitals remain *degenerate* under the influence of the negatively charged sphere. (Section 6.7)

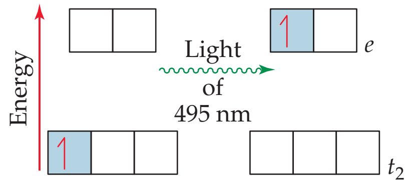
This energy picture is only a first approximation, however, because the ligands are not distributed uniformly on a spherical surface and, therefore, do not approach the metal ion equally from every direction. Instead, we envision the six ligands approaching along *x*, *y*, and *z* axes, as shown on the right in Figure 23.28. This arrangement of ligands is called an *octahedral crystal field*. Because the *d* orbitals have different orientations and shapes, they do not all experience the same repulsion from the ligands and, therefore, do not all have the same energy under the influence of the octahedral crystal field. To see why, we must consider the shapes of the *d* orbitals and how their lobes are oriented relative to the ligands.

Figure 23.28 shows that the lobes of the d_{z^2} and $d_{x^2-y^2}$ orbitals are directed *along* the *x*, *y*, and *z* axes and so point directly toward the ligand point charges. The lobes of the d_{xy}, d_{xz}, and d_{yz} orbitals, however, are directed *between* the axes and so do not point directly toward the charges. The result of this difference in orientation—$d_{x^2-y^2}$ and d_{z^2} lobes point directly toward the ligand charges; d_{xy}, d_{xz}, and d_{yz} lobes do not—is that an electron residing in either the $d_{x^2-y^2}$ or d_{z^2} orbitals feels more repulsion from the negatively charged ligands than does an electron in the d_{xy}, d_{xz}, or d_{yz} orbitals. Hence, in an octahedral crystal field, the energy of the $d_{x^2-y^2}$ and d_{z^2} orbitals is higher than the energy of the d_{xy}, d_{xz}, and d_{yz} orbitals. This difference in energy is represented by the red boxes in the energy diagram of Figure 23.28.

It might seem like the energy of the $d_{x^2-y^2}$ orbital should be different from that of the d_{z^2} orbital because the $d_{x^2-y^2}$ has four lobes pointing at ligands and the d_{z^2} has only two lobes pointing at ligands. However, the d_{z^2} orbital does have electron

Go Figure

How would you calculate the energy gap between the t_2 and e orbitals from this diagram?



▲ **Figure 23.29** **The *d–d* transition in $[Ti(H_2O)_6]^{3+}$ is produced by the absorption of 495-nm light.**

density in the *xy* plane, represented by the ring encircling the point where the two lobes meet. More advanced theory proves that, in an octahedral crystal field, the $d_{x^2-y^2}$ and d_{z^2} orbitals both have the same energy, and the d_{xy}, d_{xz}, or d_{yz} orbitals all have the same energy.

The unequal repulsion of the *d* orbitals in an octahedral crystal field leads to the splitting pattern shown in Figure 23.28. The five *d* orbitals are split into two groups: a group of three orbitals at lower energy and a group of two orbitals at higher energy. The three lower-energy *d* orbitals are called the t_2 set of orbitals, and the two higher-energy ones are called the *e* set.* The energy gap Δ between the two sets is called the *crystal-field splitting energy*.

Crystal-field theory helps us account for the colors observed in transition-metal complexes. The energy gap Δ between the t_2 and *e* sets of *d* orbitals is of the same order of magnitude as the energy of a photon of visible light. It is therefore possible for a transition-metal complex to absorb visible light that excites an electron from a lower-energy (t_2) *d* orbital into a higher-energy (*e*) *d* orbital. In $[Ti(H_2O)_6]^{3+}$, for example, the Ti(III) ion has an $[Ar]3d^1$ electron configuration. (Recall from Section 7.4 that when determining the electron configurations of transition-metal ions, we remove the *s* electrons first.) Ti(III) is thus called a d^1 *ion.* In the ground state of $[Ti(H_2O)_6]^{3+}$, the single 3*d* electron resides in an orbital in the t_2 set (**Figure 23.29**). Absorption of 495-nm light excites this electron up to an orbital in the *e* set, generating the absorption spectrum shown in Figure 23.26. Because this transition involves exciting an electron from one set of *d* orbitals to the other, we call it a ***d–d* transition**. As noted previously, the absorption of visible radiation that produces this *d–d* transition causes the $[Ti(H_2O)_6]^{3+}$ ion to appear purple.

The magnitude of the crystal-field splitting energy and, consequently, the color of a complex depend on both the metal and the ligands. For example, we saw in Figure 23.4 that the color of $[M(H_2O)_6]^{2+}$ complexes changes from reddish-pink when the metal ion is Co^{2+}, to green for Ni^{2+}, to pale blue for Cu^{2+}. If we change the ligands in the $[Ni(H_2O)_6]^{2+}$ ion, the color also changes. $[Ni(NH_3)_6]^{2+}$ has a blue-violet color, while $[Ni(en)_3]^{2+}$ is purple (**Figure 23.30**). In a ranking called the **spectrochemical series**, ligands are arranged in order of their abilities to increase the crystal-field splitting energy, as in this abbreviated list:

$$\text{—— Increasing } \Delta \longrightarrow$$

$$Cl^- < F^- < H_2O < NH_3 < en < NO_2^-(\text{N-bonded}) < CN^-$$

The magnitude of Δ increases by roughly a factor of 2 from the far left to the far right of the spectrochemical series. Ligands at the low-Δ end of the spectrochemical series are called *weak-field ligands*; those at the high-Δ end are called *strong-field ligands*.

Let's take a closer look at the colors and crystal-field splitting as we vary the ligands for the series of Ni^{2+} complexes in Figure 23.30. Because the Ni atom has an $[Ar]3d^84s^2$ electron configuration, Ni^{2+} has the configuration $[Ar]3d^8$ and therefore is a d^8 ion. The t_2 set of orbitals holds six electrons, two in each orbital, while the last two electrons go

---

* The labels t_2 for the d_{xy}, d_{xz}, and d_{yz} orbitals and *e* for the d_{z^2} and $d_{x^2-y^2}$ orbitals come from application of a branch of mathematics called *group theory* to crystal-field theory. Group theory can be used to analyze the effects of symmetry on molecular properties.

▲ **Figure 23.30** **Effect of ligand on crystal-field splitting.** The greater the crystal-field strength of the ligand, the greater the energy gap Δ it causes between the t_2 and *e* sets of the metal ion's orbitals. The increasing gap shifts the absorption maximum to shorter wavelengths.

into the *e* set of orbitals. Consistent with Hund's rule, each *e* orbital holds one electron and both electrons have the same spin. (Section 6.8)

As the ligand changes from H_2O to NH_3 to ethylenediamine, the spectrochemical series tells us that the crystal-field, Δ, exerted by the six ligands should increase. When there is more than one electron in the *d* orbitals, interactions between the electrons make the absorption spectra more complicated than the spectrum shown for $[Ti(H_2O)_6]^{3+}$ in Figure 23.26, which complicates the task of relating changes in Δ with color. With d^8 ions like Ni^{2+} three peaks are observed in the absorption spectra. Fortunately, for Ni^{2+} complexes we can simplify the analysis because only one of these three peaks falls in the visible region of the spectrum.* Because the energy separation Δ is increasing, the wavelength of the absorption peak should shift to a shorter wavelength. (Section 6.3) In the case of $[Ni(H_2O)_6]^{2+}$ the absorption peak in the visible part of the spectrum reaches a maximum near 720 nm, in the red region of the spectrum. So the complex ion takes the complementary color—green. For $[Ni(NH_3)_6]^{2+}$ the absorption peak reaches its maximum at 570 nm near the boundary between orange and yellow. The resulting color of the complex ion is a mixture of the complementary colors—blue and violet. Finally, for $[Ni(en)_3]^{2+}$ the peak shifts to an even shorter wavelength, 540 nm, which lies near the boundary between green and yellow. The resulting color purple is a mixture of the complementary colors red and violet.

Electron Configurations in Octahedral Complexes

Crystal-field theory helps us understand the magnetic properties and some important chemical properties of transition-metal ions. From Hund's rule, we expect electrons to always occupy the lowest-energy vacant orbitals first and to occupy a set of degenerate (same-energy) orbitals one at a time with their spins parallel. (Section 6.8) Thus, if we have a d^1, d^2, or d^3 octahedral complex, the electrons go into the lower-energy t_2 orbitals,

---

*The other two peaks fall in the infrared (IR) and ultraviolet (UV) regions of the spectrum. For $[Ni(H_2O)_6]^{2+}$ the IR peak is found at 1176 nm and the UV peak at 388 nm.

with their spins parallel. When a fourth electron must be added, we have the two choices shown in **Figure 23.31**: The electron can either go into an *e* orbital, where it will be the sole electron in the orbital or become the second electron in a t_2 orbital. Because the energy difference between the t_2 and *e* sets is the splitting energy Δ, the energy cost of going into an *e* orbital rather than a t_2 orbital is also Δ. Thus, the goal of filling lowest-energy available orbitals first is met by putting the electron in a t_2 orbital.

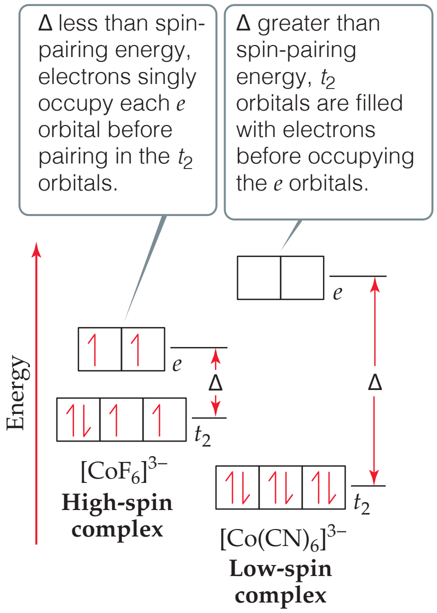
There is a penalty for doing this, however, because the electron must now be paired with the electron already occupying the orbital. The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital is called the **spin-pairing energy**. The spin-pairing energy arises from the fact that the electrostatic repulsion between two electrons that share an orbital (and so must have opposite spins) is greater than the repulsion between two electrons that are in different orbitals and have parallel spins.

In coordination complexes, the nature of the ligands and the charge on the metal ion often play major roles in determining which of the two electron arrangements shown in Figure 23.31 is used. In $[CoF_6]^{3-}$ and $[Co(CN)_6]^{3-}$, both ligands have a 1− charge. The F^- ion, however, is on the low end of the spectrochemical series, so it is a weak-field ligand. The CN^- ion is on the high end of the series and so is a strong-field ligand, which means it produces a larger energy gap Δ than the F^- ion. The splittings of the *d*-orbital energies in these two complexes are compared in **Figure 23.32**.

Cobalt(III) has an $[Ar]3d^6$ electron configuration, so both complexes in Figure 23.32 are d^6 complexes. Let's imagine that we add these six electrons one at a time to the *d* orbitals of the $[CoF_6]^{3-}$ ion. The first three go into the t_2 orbitals with their spins parallel. The fourth electron could pair up in one of the t_2 orbitals. The F^- ion is a weak-field ligand, however, and so the energy gap Δ between the t_2 set and the *e* set is small. In this case, the more stable arrangement is to place the fourth electron in one of the *e* orbitals. By the same energy argument, the fifth electron goes into the other *e* orbital. With all five *d* orbitals containing one electron, the sixth must pair up, and the energy needed to place the sixth electron in a t_2 orbital is less than that needed to place it in an *e* orbital. We end up with four t_2 electrons and two *e* electrons.

Figure 23.32 shows that the crystal-field splitting energy Δ is much larger in the $[Co(CN)_6]^{3-}$ complex. In this case, the spin-pairing energy is smaller than Δ, so the lowest-energy arrangement is to place all six electrons in the t_2 orbitals.

The $[CoF_6]^{3-}$ ion is called a **high-spin complex**; that is, the electrons are arranged so that they remain unpaired as much as possible. The $[Co(CN)_6]^{3-}$ ion is called a **low-spin complex**; that is, the electrons are arranged so that they remain paired as much as possible while still following Hund's rule. These two electronic arrangements can be



Δ less than spin-pairing energy, electrons singly occupy each *e* orbital before pairing in the t_2 orbitals.
Δ greater than spin-pairing energy, t_2 orbitals are filled with electrons before occupying the *e* orbitals.

▲ **Figure 23.32 High-spin and low-spin complexes.** The high-spin $[CoF_6]^{3-}$ ion has a weak-field ligand and so a small Δ value. The low-spin $[Co(CN)_6]^{3-}$ ion has a strong-field ligand and so a large Δ value. Because $[CoF_6]^{3-}$ has unpaired electrons, it is paramagnetic, while $[Co(CN)_6]^{3-}$ is diamagnetic.

readily distinguished by measuring the magnetic properties of each complex. Experiments show that $[CoF_6]^{3-}$ has four unpaired electrons and is paramagnetic, whereas $[Co(CN)_6]^{3-}$ has no unpaired electrons and is diamagnetic. The absorption spectrum also shows peaks corresponding to the different values of Δ in these two complexes.

In the transition-metal ions of periods 5 and 6 (which have 4*d* and 5*d* valence electrons), the *d* orbitals are larger than in the period 4 ions (which have only 3*d* electrons). Thus, ions from periods 5 and 6 interact more strongly with ligands, resulting in a larger crystal-field splittings. *Consequently, metal ions in periods 5 and 6 are invariably low spin in an octahedral crystal field.*

Sample Exercise 23.7

The Spectrochemical Series, Crystal-Field Splitting, Color, and Magnetism

The compound hexaamminecobalt(III) chloride is diamagnetic and orange in color with a single absorption peak in its visible absorption spectrum. (**a**) What is the electron configuration of the cobalt(III) ion? (**b**) Is $[Co(NH_3)_6]^{3+}$ a high-spin complex or a low-spin complex? (**c**) Estimate the wavelength where you expect the absorption of light to reach a maximum? (**d**) What color and magnetic behavior would you predict for the complex ion $[Co(en)_3]^{3+}$?

SOLUTION

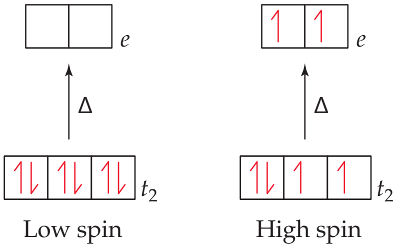
Analyze We are given the color and magnetic behavior of an octahedral complex containing Co with a +3 oxidation number. We need to use this information to determine its electron configuration, its spin state (low-spin or high-spin), and the color of light it absorbs. In part (d), we must use the spectrochemical series to predict how its properties will change if NH_3 is replaced by ethylenediamine (en).

Plan (**a**) From the oxidation number and the periodic table we can determine the number of valence electrons for Co(III), and from that we can determine the electron configuration. (**b**) The magnetic behavior can be used to determine whether this compound is a low-spin or high-spin complex. (**c**) Because there is a single peak in the visible absorption spectrum, the color of the compound should be complementary to the color of light that is absorbed most strongly. (**d**) Ethylenediamine is a stronger field ligand than NH_3, so we expect a larger Δ for $[Co(en)_3]^{3+}$ than for $[Co(NH_3)_6]^{3+}$.

Solve

(**a**) Co has an electron configuration of $[Ar]4s^2 3d^7$, and Co^{3+} has three fewer electrons than Co. Because transition-metal ions always lose their valence shell *s* electrons, the electron configuration of Co^{3+} is $[Ar]3d^6$.

(**b**) There are six valence electrons in the *d* orbitals. The filling of the t_2 and *e* orbitals for both high-spin and low-spin complexes is shown below. Because the compound is diamagnetic, we know all of the electrons must be paired up, which allows us to determine that $[Co(NH_3)_6]^{3+}$ is a low-spin complex.



Low spin High spin

(**c**) We are told that the compound is orange and has a single absorption peak in the visible region of the spectrum. The compound must therefore absorb the complementary color of orange, which is blue. The blue region of the spectrum ranges from approximately 430 nm to 490 nm. As an estimate, we assume that the complex ion absorbs somewhere in the middle of the blue region, near 460 nm.

(**d**) Ethylenediammine is higher in the spectrochemical series than ammonia. Therefore, we expect a larger Δ for $[Co(en)_3]^{3+}$. Because Δ was already greater than the spin-pairing energy for $[Co(NH_3)_6]^{3+}$, we expect $[Co(en)_3]^{3+}$ to be a low-spin complex as well, with a d^6 configuration, so it will also be diamagnetic. The wavelength at which the complex absorbs light will shift to higher energy. If we assume a shift in the absorption maximum from blue to violet, the color of the complex will become yellow.

Comment The compound $[Co(en)_3]Cl_3$, which contains the $[Co(en)_3]^{3+}$ ion, was made and studied by Alfred Werner. This compound forms diamagnetic, golden-yellow crystals.

Practice Exercise

Consider the colors of the ammonia complexes of Co^{3+} given in Table 23.3. Based on the change in color would you expect $[Co(NH_3)_5Cl]^{2+}$ to have a larger or smaller value of Δ than $[Co(NH_3)_6]^{3+}$? Is this prediction consistent with the spectrochemical series?

▲ **Figure 23.33** **Energies of the *d* orbitals in a tetrahedral crystal field.** The splitting of the *e* and t_2 sets of orbitals is inverted with respect to the splitting associated with an octahedral crystal field. The crystal-field splitting energy Δ is smaller than it is in an octahedral crystal field.

Tetrahedral and Square-Planar Complexes

Thus far we have considered crystal-field theory only for complexes having an octahedral geometry. When there are only four ligands in a complex, the geometry is generally tetrahedral, except for the special case of d^8 metal ions, which we discuss in a moment.

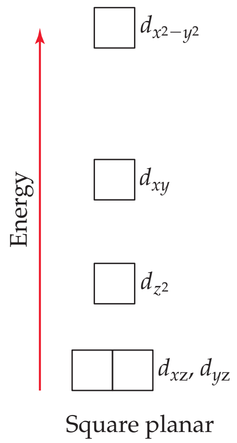
The crystal-field splitting of *d* orbitals in tetrahedral complexes differs from that in octahedral complexes. Four equivalent ligands can interact with a central metal ion most effectively by approaching along the vertices of a tetrahedron. In this geometry, the lobes of the two *e* orbitals point toward the edges of the tetrahedron, exactly in between the ligands (**Figure 23.33**). This orientation keeps the $d_{x^2-y^2}$ and d_{z^2} as far from the ligand point charges as possible. Consequently, these two *d* orbitals experience less repulsion from the ligands and lie at lower energy than the other three *d* orbitals. The three t_2 orbitals do not point directly at the ligand point charges, but they do come closer to the ligands than the *e* set, and as a result they experience more repulsion and are higher in energy. As we see in Figure 23.33, the splitting of *d* orbitals in a tetrahedral geometry is the opposite of what we find for the octahedral geometry: the *e* orbitals are now *below* the t_2 orbitals. The crystal-field splitting energy Δ is much smaller for tetrahedral complexes than it is for comparable octahedral complexes, in part because there are fewer ligand point charges in the tetrahedral geometry, and in part because neither set of orbitals has lobes that point directly at the ligands. Calculations show that for the same metal ion and ligand set, Δ for the tetrahedral complex is only four-ninths as large as for the octahedral complex. For this reason, nearly all tetrahedral complexes are high spin; the crystal-field splitting energy is never large enough to overcome the spin-pairing energies.

In a square-planar complex, four ligands are arranged about the metal ion such that all five species are in the *xy* plane. The resulting energy levels of the *d* orbitals are illustrated in **Figure 23.34**. Note in particular that the d_{z^2} orbital is considerably lower in energy than the $d_{x^2-y^2}$ orbital. To understand why this is so, recall from Figure 23.28 that in an octahedral field the d_{z^2} orbital of the metal ion interacts with the ligands positioned above and below the *xy* plane. There are no ligands in these two positions in a square-planar complex, which means that the d_{z^2} orbital experiences less repulsion and so remains in a lower-energy, more stable state.

Square-planar complexes are characteristic of metal ions with a d^8 electron configuration. They are nearly always low spin, with the eight *d* electrons spin-paired to form a diamagnetic complex. This pairing leaves the $d_{x^2-y^2}$ orbital empty. Such an electronic arrangement is particularly common among the d^8 ions of periods 5 and 6, such as Pd^{2+}, Pt^{2+}, Ir^{+}, and Au^{3+}.

Go Figure

For which *d* orbital(s) do the lobes point directly at the ligands in a square-planar crystal field?



▲ **Figure 23.34** **Energies of the *d* orbitals in a square-planar crystal field.**

Sample Exercise 23.8

Populating *d* Orbitals in Tetrahedral and Square-Planar Complexes

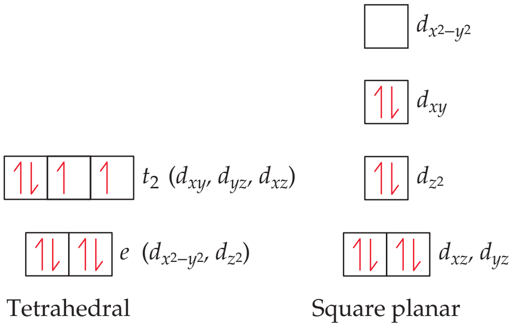
Nickel(II) complexes in which the metal coordination number is 4 can have either square-planar or tetrahedral geometry. $[NiCl_4]^{2-}$ is paramagnetic, and $[Ni(CN)_4]^{2-}$ is diamagnetic. One of these complexes is square planar, and the other is tetrahedral. Use the relevant crystal-field splitting diagrams in the text to determine which complex has which geometry.

SOLUTION

Analyze We are given two complexes containing Ni^{2+} and their magnetic properties. We are given two molecular geometry choices and asked to use crystal-field splitting diagrams from the text to determine which complex has which geometry.

Plan We need to determine the number of *d* electrons in Ni^{2+} and then use Figure 23.33 for the tetrahedral complex and Figure 23.34 for the square-planar complex.

Solve Nickel(II) has the electron configuration $[Ar]3d^8$. With very few exceptions, tetrahedral complexes are high spin and square-planar complexes are low spin. Therefore, the population of the *d* orbitals in the two geometries is



The tetrahedral complex has two unpaired electrons, and the square-planar complex has none. Hence, the tetrahedral complex must be paramagnetic and the square planar must be diamagnetic. Therefore, $[NiCl_4]^{2-}$ is tetrahedral, and $[Ni(CN)_4]^{2-}$ is square planar.

Comment Nickel(II) forms octahedral complexes more frequently than square-planar ones, whereas d^8 metals from periods 5 and 6 tend to favor square-planar coordination.

▶ Practice Exercise

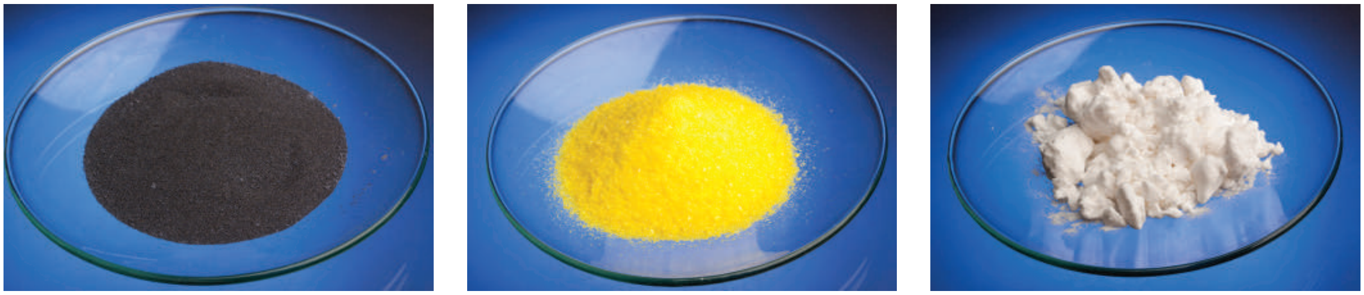
Are there any diamagnetic tetrahedral complexes containing transition-metal ions with partially filled *d* orbitals? If so what electron count(s) leads to diamagnetism?

Crystal-field theory can be used to explain many observations in addition to those we have discussed. The theory is based on electrostatic interactions between ions and atoms, which essentially means ionic bonds. Many lines of evidence show, however, that the bonding in complexes must have some covalent character. Therefore, molecular-orbital theory (Sections 9.7 and 9.8) can also be used to describe the bonding in complexes, but the application of molecular-orbital theory to coordination compounds is beyond the scope of our discussion. Crystal-field theory, though not entirely accurate in all details, provides an adequate and useful first description of the electronic structure of complexes.

A CLOSER LOOK Charge-Transfer Color

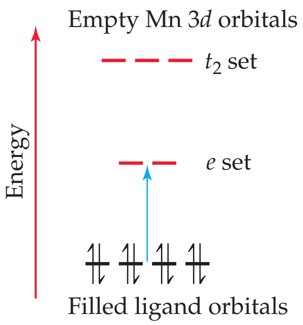
In the laboratory portion of your course, you have probably seen many colorful transition-metal compounds, including those shown in **Figure 23.35**. Many of these compounds are colored because of *d–d* transitions. Some colored complexes, however, including the violet permanganate ion, MnO_4^-, and the yellow chromate ion, CrO_4^{2-}, derive their color from a different type of excitation involving the *d* orbitals.

The permanganate ion strongly absorbs visible light, with a maximum absorption at 565 nm. Because violet is complementary to yellow, this strong absorption in the yellow portion of the



$KMnO_4$ K_2CrO_4 $KClO_4$

▲ **Figure 23.35 The colors of compounds can arise from charge-transfer transitions.** $KMnO_4$ and K_2CrO_4 are colored due to ligand-to-metal charge-transfer transitions in their anions. Higher-energy ultraviolet photons are needed to excite the charge-transfer transition in the perchlorate ion, so $KClO_4$ is white.



▲ **Figure 23.36 Ligand-to-metal charge-transfer transition in MnO_4^-.** As shown by the blue arrow, an electron is excited from a nonbonding orbital on O into one of the empty *d* orbitals on Mn.

visible spectrum is responsible for the violet color of salts and solutions of the ion. What is happening during this absorption of light? The MnO_4^- ion is a complex of Mn(VII). Mn(VII) has a [Ar]$3d^0$ electron configuration, so the absorption cannot be due to a *d–d* transition because there are no *d* electrons to excite! That does not mean, however, that the *d* orbitals are not involved in the transition. The excitation in the MnO_4^- ion is due to a *charge-transfer transition*, in which an electron on one oxygen ligand is excited into a vacant *d* orbital on the Mn ion (Figure 23.36). In essence, an electron is transferred from a ligand to the metal, so this transition is called a *ligand-to-metal charge-transfer (LMCT) transition*.

An LMCT transition is also responsible for the color of the CrO_4^{2-}, which contains the Cr(VI) ion, also with an [Ar]$3d^0$ electron configuration.

Also shown in Figure 23.35 is a salt of the perchlorate ion, ClO_4^-. Like MnO_4^-, ClO_4^- is tetrahedral and has its central atom in the +7 oxidation state. However, because the Cl atom does not have low-lying *d* orbitals, exciting an electron from O to Cl requires a more energetic photon than it does in MnO_4^-. The first absorption for ClO_4^- is in the ultraviolet portion of the spectrum, so no visible light is absorbed and the salt appears white.

Other complexes exhibit charge-transfer excitations in which an electron from the metal atom is excited to an empty orbital on a ligand. Such an excitation is called a *metal-to-ligand charge-transfer (MLCT) transition*.

Charge-transfer transitions are generally more intense than *d–d* transitions. Many metal-containing pigments used for oil painting, such as cadmium yellow (CdS), chrome yellow ($PbCrO_4$), and red ochre (Fe_2O_3), have intense colors because of charge-transfer transitions.

Self-Assessment Exercises

SAE 23.16 Which of the following statements about crystal-field theory applied to octahedral complexes is *false*?

(a) In crystal-field theory, the ligands are modeled as point negative charges.
(b) In an octahedral crystal field, the ligands are assumed to lie on the $\pm x$, $\pm y$, and $\pm z$ axes.
(c) In an octahedral crystal field, the *d* orbitals split into a set of three orbitals at lower energy and a set of two orbitals at higher energy.
(d) In an octahedral crystal field, the d_{xy} orbital is higher in energy than the d_{xz} orbital.

SAE 23.17 As discussed in the text, a solution of $[Ti(H_2O)_6]^{3+}$ absorbs light of wavelength 495 nm. Which of the following statements about this observation is or are *true*?

(i) Because the absorption is in the visible portion of the spectrum, the solution will have color.
(ii) $[Ti(H_2O)_6]^{3+}$ is an example of a d^2 transition-metal complex.
(iii) The transition is an example of a *d–d* transition in which an electron is excited from the t_2 set of orbitals to the *e* set of orbitals.

(a) Only statement i is true. **(b)** Statements i and ii are true. **(c)** Statements i and iii are true. **(d)** Statements ii and iii are true. **(e)** All three statements are true.

SAE 23.18 Which of the following cobalt(III) complexes has the largest crystal-field splitting energy?

(a) $[Co(NH_3)_6]^{3+}$
(b) $[CoF_6]^{3-}$
(c) $[Co(en)_3]^{3+}$
(d) $[Co(H_2O)_6]^{3+}$
(e) $[Co(CN)_6]^{3-}$

SAE 23.19 Beakers A, B, and C contain solutions of octahedral complexes of the same transition metal in the same oxidation state, but with different ligands. Each solution undergoes the same *d-d* transition, and the colors of the solutions are yellow-orange for Beaker A, green for Beaker B, and blue-violet for Beaker C. What is the order of the solutions in Beakers A, B, and C from weakest- to strongest-field ligand?

(a) B < C < A
(b) A < C < B
(c) C < B < A
(d) A < B < C

SAE 23.20 Cobalt(II) forms both high-spin and low-spin octahedral complexes. Complete the following: The high-spin Co(II) complexes will have ______ unpaired electrons, whereas the low-spin complexes will have ______ unpaired electrons. **(a)** 1, 3 **(b)** 2, 1 **(c)** 3, 1 **(d)** 4, 0 **(e)** 5, 6

SAE 23.21 Which of the following statements about the application of crystal-field theory to tetrahedral and square-planar complexes is *false*?

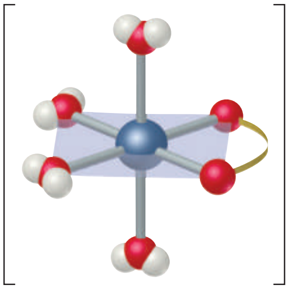
(a) The splitting of the *d* orbitals in a tetrahedral complex has a set of two orbitals at lower energy and a set of three orbitals at higher energy.
(b) Tetrahedral complexes are almost always low-spin complexes.
(c) For a given ligand, the magnitude of the crystal-field splitting energy in a tetrahedral complex is less than that in an octahedral complex.
(d) In a square-planar complex, the energy of the d_{z^2} orbital is lower than that of the $d_{x^2-y^2}$ orbital.
(e) A d^8 square-planar complex has four filled *d* orbitals and one empty *d* orbital.

Putting Concepts Together

The oxalate ion has the Lewis structure shown in Table 23.4. (**a**) Show the geometry of the complex formed when this ion complexes with cobalt(II) to form $[Co(C_2O_4)(H_2O)_4]$. (**b**) Write the formula for the salt formed when three oxalate ions complex with Co(II), assuming that the charge-balancing cation is Na^+. (**c**) Sketch all the possible geometric isomers for the cobalt complex formed in part (b). Are any of these isomers chiral? Explain. (**d**) The equilibrium constant for the formation of the cobalt(II) complex produced by coordination of three oxalate anions, as in part (b), is 5.0×10^9, and the equilibrium constant for formation of the cobalt(II) complex with three molecules of *ortho*-phenanthroline (Table 23.4) is 9×10^{19}. From these results, what conclusions can you draw regarding the relative Lewis base properties of the two ligands toward cobalt(II)? (**e**) Using the approach described in Sample Exercise 17.16, calculate the concentration of free aqueous Co(II) ion in a solution initially containing 0.040 *M* oxalate (*aq*) and 0.0010 *M* $Co^{2+}(aq)$.

SOLUTION

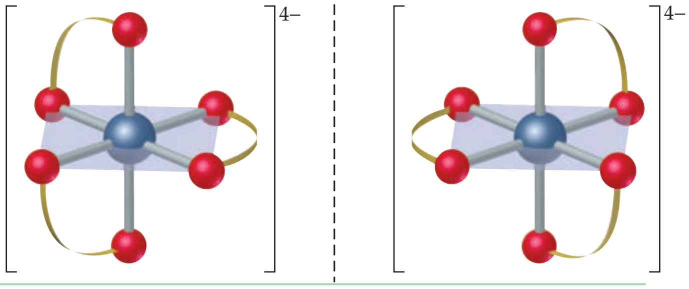
(**a**) The complex formed by coordination of one oxalate ion is octahedral:



(**b**) Because the oxalate ion has a charge of 2−, the net charge of a complex with three oxalate anions and one Co^{2+} ion is 4−. Therefore, the coordination compound has the formula:

$Na_4[Co(C_2O_4)_3]$

(**c**) There is only one geometric isomer. The complex is chiral, however, in the same way the $[Co(en)_3]^{3+}$ complex is chiral (Figure 23.22). The two mirror images are not superimposable, so there are two enantiomers:



(**d**) The *ortho*-phenanthroline ligand is bidentate, like the oxalate ligand, so they both exhibit the chelate effect. Thus, we conclude that *ortho*-phenanthroline is a stronger Lewis base toward Co^{2+} than oxalate. This conclusion is consistent with what we learned about bases in Section 16.7, that nitrogen bases are generally stronger than oxygen bases. (Recall, for example, that NH_3 is a stronger base than H_2O.)

(**e**) The equilibrium we must consider involves 3 mol of oxalate ion (represented as ox^{2-}).

$$Co^{2+}(aq) + 3\,ox^{2-}(aq) \rightleftharpoons [Co(ox)_3]^{4-}(aq)$$

The formation-constant expression is:

$$K_f = \frac{[[Co(ox)_3]^{4-}]}{[Co^{2+}][ox^{2-}]^3}$$

Because K_f is so large, we can assume that essentially all the Co^{2+} is converted to the oxalato complex. Under that assumption, the final concentration of $[Co(ox)_3]^{4-}$ is 0.0010 *M* and that of oxalate ion is $[ox^{2-}] = (0.040) - 3(0.0010) = 0.037\ M$ (three ox^{2-} ions react with each Co^{2+} ion). We then have:

$$[Co^{2+}] = x\ M,\ [ox^{2-}] \cong 0.037\ M,\ [[Co(ox)_3]^{4-}] \cong 0.0010\ M$$

Inserting these values into the equilibrium-constant expression, and solving for x, we obtain $4 \times 10^{-9}\ M$. From this, we see that the oxalate has complexed all but a tiny fraction of the Co^{2+} in solution.

$$K_f = \frac{(0.0010)}{x(0.037)^3} = 5 \times 10^9$$

$$x = 4 \times 10^{-9}\ M$$

Chapter Summary and Key Terms

THE TRANSITION METALS (SECTION 23.1) Metallic elements are obtained from **minerals**, which are solid inorganic compounds found in nature. **Metallurgy** is the science and technology of extracting metals from the earth and processing them for further use. Transition metals are characterized by incomplete filling of the *d* orbitals. The presence of *d* electrons in transition elements leads to multiple oxidation states. As we proceed through the transition metals in a given row of the periodic table, the attraction between the nucleus and the valence electrons increases more markedly for *d* electrons than for *s* electrons. As a result, the later transition elements in a period tend to have lower oxidation states.

The atomic and ionic radii of period 5 transition metals are larger than those of period 4 metals. The transition metals of periods 5 and 6 have comparable atomic and ionic radii and are also similar in other properties. This similarity is due to the **lanthanide contraction**.

The presence of unpaired electrons in valence orbitals leads to magnetic behavior in transition metals and their compounds. In **ferromagnetic**, **ferrimagnetic**, and **antiferromagnetic** substances, the unpaired electron spins on atoms in a solid are affected by spins on neighboring atoms. In a ferromagnetic substance, the spins all point in the same direction. In an antiferromagnetic substance, the spins point in opposite directions and cancel one another. In a ferrimagnetic substance, the spins point in opposite directions but do not fully cancel. Ferromagnetic and ferrimagnetic substances are used to make permanent magnets.

TRANSITION-METAL COMPLEXES (SECTION 23.2) **Coordination compounds** are substances that contain **metal complexes**. Metal complexes contain metal ions bonded to several surrounding anions or molecules known as **ligands**. The metal ion and its ligands make up the **coordination sphere** of the complex. The number of atoms attached to the metal ion is the **coordination number** of the metal ion. The most common coordination numbers are 4 and 6; the most common coordination geometries are tetrahedral, square planar, and octahedral.

COMMON LIGANDS IN COORDINATION CHEMISTRY (SECTION 23.3) Ligands that occupy only one site in a coordination sphere are called **monodentate ligands**. The atom of the ligand that bonds to the metal ion is the **donor atom**. Ligands that have two donor atoms are **bidentate ligands**. **Polydentate ligands** have three or more donor atoms. Bidentate and polydentate ligands are also called **chelating agents**. In general, chelating agents form more stable complexes than do related monodentate ligands, an observation known as the **chelate effect**. Many biologically important molecules, such as the **porphyrins**, are complexes of chelating agents. A related group of plant pigments known as **chlorophylls** are important in **photosynthesis**, the process by which plants use solar energy to convert CO_2 and H_2O into carbohydrates.

NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY (SECTION 23.4) In naming coordination compounds, the number and type of ligands attached to the metal ion are specified, as is the oxidation state of the metal ion. **Isomers** are compounds with the same composition but different arrangements of atoms and therefore different properties. **Structural isomers** differ in the bonding arrangements of the ligands. **Linkage isomerism** occurs when a ligand can coordinate to a metal ion through different donor atoms. **Coordination-sphere isomers** contain different ligands in the coordination sphere. **Stereoisomers** are isomers with the same chemical bonding arrangements but different spatial arrangements of ligands. The most common forms of stereoisomerism are **geometric isomerism** and **optical isomerism**. Geometric isomers differ from one another in the relative locations of donor atoms in the coordination sphere; the most common are cis and trans isomers. Geometric isomers differ from one another in their chemical and physical properties. Optical isomers are nonsuperimposable mirror images of each other. Optical isomers, or **enantiomers**, are **chiral**, meaning that they have a specific “handedness” and differ only in the presence of a chiral environment. Optical isomers can be distinguished from one another by their interactions with plane-polarized light; solutions of one isomer rotate the plane of polarization to the right (**dextrorotatory**), whereas solutions of its mirror image rotate the plane to the left (**levorotatory**). Chiral molecules, therefore, are **optically active**. A 50–50 mixture of two optical isomers does not rotate plane-polarized light and is said to be **racemic**.

COLOR AND MAGNETISM IN COORDINATION CHEMISTRY (SECTION 23.5) A substance has a particular color because it either reflects or transmits light of that color or absorbs light of the **complementary color**. The amount of light absorbed by a sample as a function of wavelength is known as its **absorption spectrum**. The light absorbed provides the energy to excite electrons to higher-energy states.

It is possible to determine the number of unpaired electrons in a complex from its degree of paramagnetism. Compounds with no unpaired electrons are diamagnetic.

CRYSTAL-FIELD THEORY (SECTION 23.6) **Crystal-field theory** successfully accounts for many properties of coordination compounds, including their color and magnetism. In crystal-field theory, the interaction between metal ion and ligand is viewed as electrostatic. Because some *d* orbitals point directly at the ligands whereas others point between them, the ligands split the energies of the metal *d* orbitals. For an octahedral complex, the *d* orbitals are split into a lower-energy set of three degenerate orbitals (the t_2 set) and a higher-energy set of two degenerate orbitals (the *e* set). Visible light can cause a ***d–d* transition**, in which an electron is excited from a lower-energy *d* orbital to a higher-energy *d* orbital. The **spectrochemical series** lists ligands in order of their ability to increase the split in *d*-orbital energies in octahedral complexes.

Strong-field ligands create a splitting of *d*-orbital energies that is large enough to overcome the **spin-pairing energy**. The *d* electrons then preferentially pair up in the lower-energy orbitals, producing a **low-spin complex**. When the ligands exert a weak crystal field, the splitting of the *d* orbitals is small. The electrons then occupy the higher-energy *d* orbitals in preference to pairing up in the lower-energy set, producing a **high-spin complex**. Transition-metal ions from periods 5 and 6 have large crystal-field splitting energies and adopt low-spin configurations in octahedral complexes.

Crystal-field theory also applies to tetrahedral and square-planar complexes, which leads to different *d*-orbital splitting patterns. In a tetrahedral crystal field, the splitting of the *d* orbitals results in a higher-energy t_2 set and a lower-energy *e* set, the opposite of the octahedral case. The splitting in a tetrahedral crystal field is much smaller than that in an octahedral crystal field, so tetrahedral complexes are nearly always high-spin complexes.

Exam Prep

EP 23.1 A certain transition-metal element exhibits the following properties: (i) Its maximum positive oxidation state is +5. (ii) Its metallic radius is greater than that of the element immediately to its right in the periodic table. (iii) Its metallic radius is nearly identical to that of the element immediately below it in the periodic table. What is the identity of the element? (**a**) vanadium (**b**) manganese (**c**) niobium (**d**) technetium (**e**) rhodium

EP 23.2 In which of the following compounds does the transition metal have the highest oxidation state?

(**a**) $[Co(NH_3)_4Cl_2]$

(**b**) $K_2[PtCl_6]$

(**c**) $Rb_3[MoO_3F_3]$

(**d**) $Na[Ag(CN)_2]$

(**e**) $K_4[Mn(CN)_6]$

EP 23.3 What is the ground-state valence electron configuration for Ru^{2+}? (**a**) $[Kr]5s^24d^6$ (**b**) $[Kr]4d^6$ (**c**) $[Kr]5s^24d^4$ (**d**) $[Kr]4d^8$

EP 23.4 Which type of magnetic behavior is described by the following statement? "In this phenomenon, the spins of the atoms and ions in the solid are all aligned parallel to one another." (**a**) paramagnetism (**b**) diamagnetism (**c**) ferrimagnetism (**d**) ferromagnetism (**e**) antiferromagnetism

EP 23.5 When the compound $RhCl_3 \cdot 4\,NH_3$ is dissolved in water and treated with excess $AgNO_3(aq)$, one mole of $AgCl(s)$ is formed for every mole of $RhCl_3 \cdot 4\,NH_3$. What is the correct way to write the formula of this compound?

(**a**) $[Rh(NH_3)_4Cl_3]$

(**b**) $[RhCl_3](NH_3)_4$

(**c**) $[Rh(NH_3)_4Cl]Cl_2$

(**d**) $[Rh(NH_3)_4]Cl_3$

(**e**) $[Rh(NH_3)_4Cl_2]Cl$

EP 23.6 Which of the following statements about metal–ligand bonding is or are *true*?

(**i**) The metal–ligand bond can be described as a Lewis acid–base interaction.

(**ii**) Ligands must have a negative charge.

(**iii**) To act as a ligand, a molecule or ion must have a lone pair of electrons.

(**a**) Only one statement is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 23.7 Which of the following statements about ligands is *false*?

(**a**) Bipyridine is a monodentate ligand.

(**b**) The chelate effect leads to a special stability of complexes formed with bidentate and polydentate ligands.

(**c**) The EDTA ligand has both nitrogen and oxygen donor atoms.

(**d**) The diethylenetriamine ligand has three donor atoms.

(**e**) A coordination complex with three bidentate ligands has a coordination number of six.

EP 23.8 Which of the following ligands does *not* have a nitrogen atom that can serve as a donor atom? (**a**) thiocyanate ion (**b**) ethylenediamine (**c**) bipyridine (**d**) nitrite ion (**e**) oxalate ion

EP 23.9 What is the name of the compound $[Rh(NH_3)_4Cl_2]Cl$?

(**a**) rhodium(III) tetraamminedichloro chloride (**b**) tetraammoniadichlororhodium(III) chloride (**c**) tetraamminedichlororhodium(III) chloride (**d**) tetraamminetrichloro-rhodium(III) (**e**) tetraamminedichlororhodium(II) chloride

EP 23.10 What is the chemical formula for the compound sodium tetracyanoplatinate(II)?

(**a**) $Na[Pt(CN)_4]$

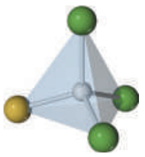
(**b**) $Na_2[Pt(CN)_4]$

(**c**) $Na_4[Pt(CN)_4]$

(**d**) $Na_2[Pt(CN)_6]$

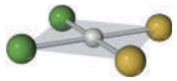
(**e**) $Na_4[Pt(CN)_6]$

EP 23.11 Which of the following molecules does *not* have a geometric isomer?



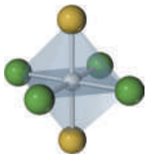
$[MX_3Y]$

(**a**)



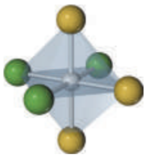
$[MX_2Y_2]$

(**b**)



$[MX_4Y_2]$

(**c**)



$[MX_3Y_3]$

(**d**)

EP 23.12 Which of the following complexes has an optical isomer?

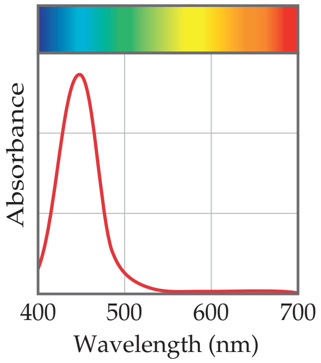
(**a**) tetrahedral $[CdBr_2Cl_2]^{2-}$

(**b**) octahedral $[CoCl_4(en)]^{2-}$

(**c**) octahedral $[Co(NH_3)_4Cl_2]^{2+}$

(**d**) tetrahedral $[Co(NH_3)BrClI]^{-}$

EP 23.13 A solution containing a certain transition-metal complex ion has the absorption spectrum shown here.



What color would you expect a solution containing this ion to be? (**a**) violet (**b**) blue (**c**) green (**d**) orange (**e**) red

EP 23.14 Which of the following statements about crystal-field theory is or are *true*?

(**i**) In an octahedral crystal field, the five *d* orbitals remain degenerate.

(**ii**) In an octahedral crystal field, the t_2 set of orbitals is lower in energy than the *e* set of orbitals.

(**iii**) The crystal-field splitting energy is the separation between the t_2 and *e* sets of orbitals.

(**a**) Only one statement is true. (**b**) Statements i and ii are true. (**c**) Statements i and iii are true. (**d**) Statements ii and iii are true. (**e**) All three statements are true.

EP 23.15 When a d^1 octahedral metal complex undergoes a *d–d* transition, the electron is excited from the ______ to the ______.

(**a**) t_2 set of orbitals, *e* set of orbitals (**b**) *e* set of orbitals, t_2 set of orbitals (**c**) t_2 set of orbitals, *s* orbital (**d**) *s* orbital, *e* set of orbitals (**e**) *e* set of orbitals, *s* orbital

EP 23.16 An aqueous solution of $[Co(H_2O)_6]^{3+}$ is blue. When the H_2O ligands are replaced with a certain ligand X, the solution turns green. When the H_2O ligands are replaced with a different ligand Y, the solution turns purple. What are the positions of ligands X and Y on the spectrochemical series relative to H_2O?

(**a**) $X < Y < H_2O$

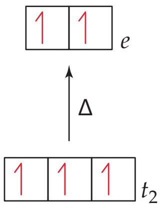
(**b**) $H_2O < Y < X$

(**c**) $H_2O < X < Y$

(**d**) $Y < H_2O < X$

(**e**) $H_2O < X < Y$

EP 23.17 The energy-level diagram for the octahedral complex $[Fe(H_2O)_6]^{3+}$ is shown here. When the H_2O ligands are replaced with CN^- ligands, the low-spin complex $[Fe(CN)_6]^{3-}$ is formed. Which of the following will be different between $[Fe(H_2O)_6]^{3+}$ and $[Fe(CN)_6]^{3-}$?



(i) the color of the complex
(ii) the number of unpaired electrons
(iii) the crystal-field splitting energy (Δ)

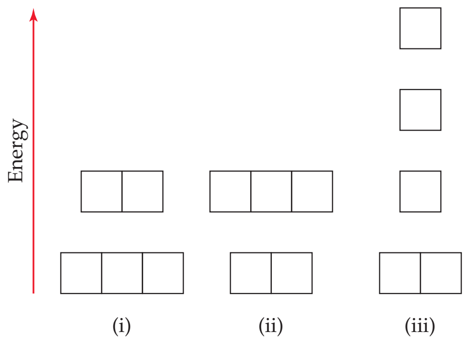
(**a**) i only (**b**) i and ii (**c**) i and iii (**d**) ii and iii (**e**) i, ii, and iii

EP 23.18 Which of the following octahedral complex ions will have the fewest number of unpaired electrons?

(**a**) $[Cr(H_2O)_6]^{3+}$
(**b**) $[V(H_2O)_6]^{3+}$
(**c**) $[FeF_6]^{3-}$
(**d**) $[RhCl_6]^{3-}$
(**e**) $[Ni(NH_3)_6]^{2+}$

EP 23.19 How many unpaired electrons do you predict for the tetrahedral $[MnCl_4]^{2-}$ ion? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

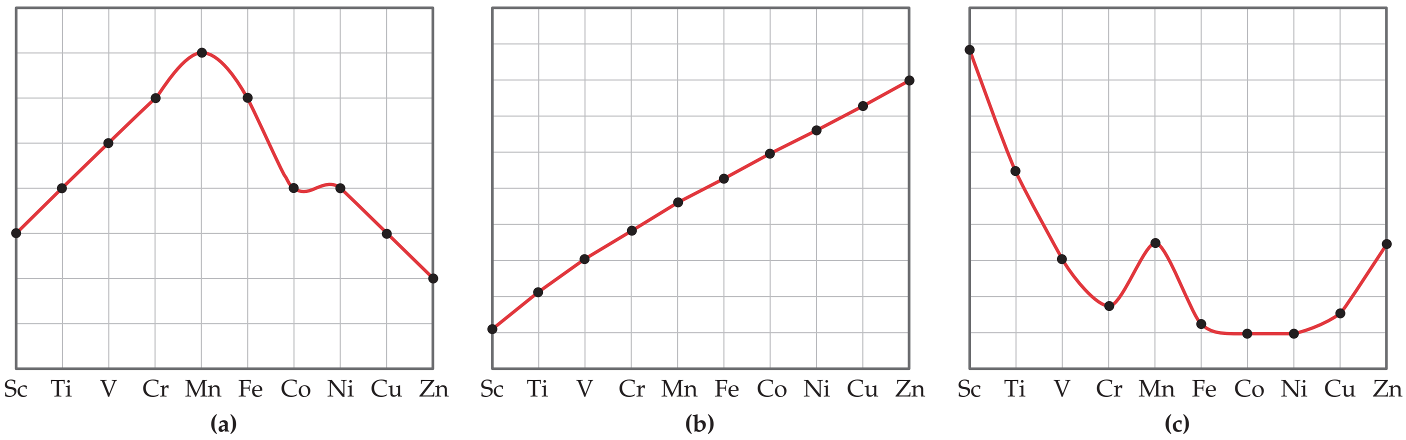
EP 23.20 The crystal-field energy levels are given here for three different geometries. Which geometry corresponds to diagrams i, ii, and iii? (**a**) octahedral, tetrahedral, square planar (**b**) octahedral, square planar, tetrahedral (**c**) tetrahedral, octahedral, square planar (**d**) tetrahedral, square planar, octahedral (**e**) square planar, tetrahedral, octahedral



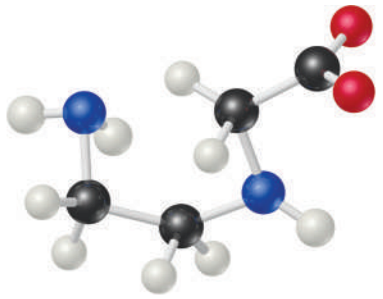
Exercises

Visualizing Concepts

23.1 The three graphs below show the variation in radius, effective nuclear charge, and maximum oxidation state for the transition metals of period 4. In each part below, identify which property is being plotted. [Section 23.1]



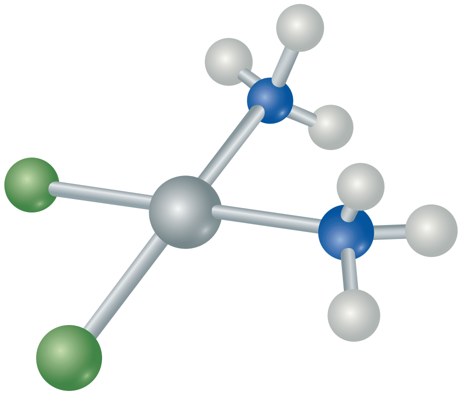
23.2 Draw the structure for $Pt(en)Cl_2$ and use it to answer the following questions: (**a**) What is the coordination number for platinum in this complex? (**b**) What is the coordination geometry? (**c**) What is the oxidation state of the platinum? (**d**) How many unpaired electrons are there? [Sections 23.2 and 23.6]



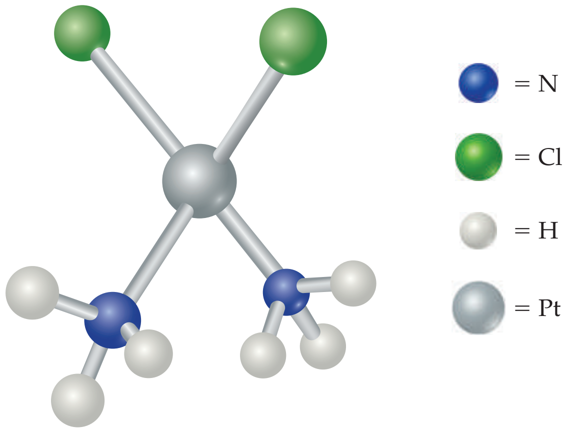
$NH_2CH_2CH_2NHCH_2CO_2^-$

23.3 Draw the Lewis structure for the ligand shown here. (**a**) Which atoms can serve as donor atoms? Classify this ligand as monodentate, bidentate, or polydentate. (**b**) How many of these ligands are needed to fill the coordination sphere in an octahedral complex? [Section 23.2]

23.4 Four-coordinate metals can have either a tetrahedral or a square-planar geometry; both possibilities are shown here for $[PtCl_2(NH_3)_2]$. (**a**) What is the name of this molecule? (**b**) Would the tetrahedral molecule have a geometric isomer? (**c**) Would the tetrahedral molecule be diamagnetic or paramagnetic? (**d**) Would the square-planar molecule have a geometric isomer? (**e**) Would the square-planar molecule be diamagnetic or paramagnetic? (**f**) Would determining the number of geometric isomers help you distinguish between the tetrahedral and square-planar geometries? (**g**) Would measuring the molecule's response to a magnetic field help you distinguish between the two geometries? [Sections 23.4–23.6]

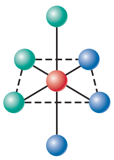


square planar

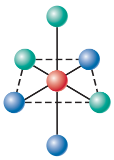


tetrahedral

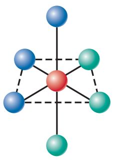
23.5 There are two geometric isomers of octahedral complexes of the type MA_3X_3, where M is a metal and A and X are monodentate ligands. Of the complexes shown here, which are identical to (1) and which are the geometric isomers of (1)? [Section 23.4]



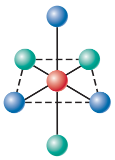
(1)



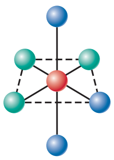
(2)



(3)



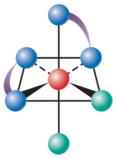
(4)



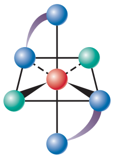
(5)

23.6 Which of the complexes shown here are chiral? [Section 23.4]

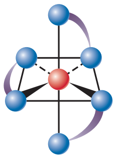
● = Cr ●⌒● = $NH_2CH_2CH_2NH_2$ ● = Cl ● = NH_3



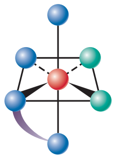
(1)



(2)

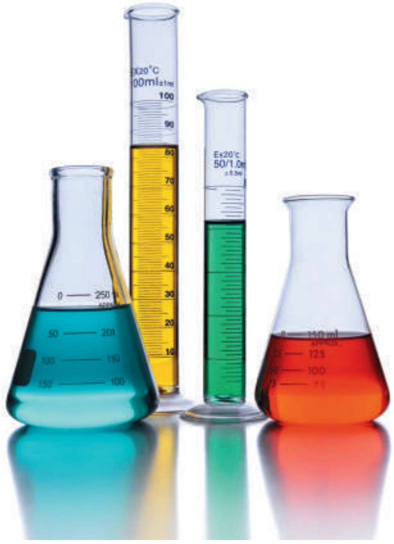


(3)

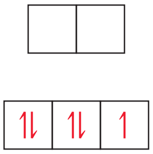


(4)

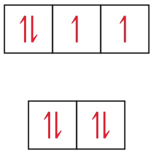
23.7 The solutions shown here each have an absorption spectrum with a single absorption peak like that shown in Figure 23.26. What color does each solution absorb most strongly? [Section 23.5]



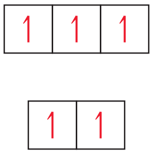
23.8 Which of these crystal-field splitting diagrams represents: (**a**) a weak-field octahedral complex of Fe^{3+}, (**b**) a strong-field octahedral complex of Fe^{3+}, (**c**) a tetrahedral complex of Fe^{3+}, (**d**) a tetrahedral complex of Ni^{2+}? (The diagrams do not indicate the relative magnitudes of Δ.) [Section 23.6]



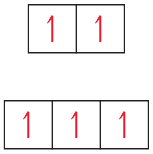
(1)



(2)

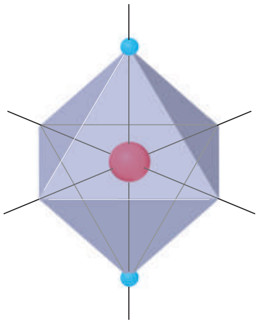


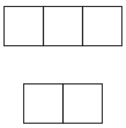
(3)



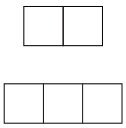
(4)

23.9 In the linear crystal-field shown here, the negative charges are on the *z* axis. Using Figure 23.28 as a guide, predict which of the following choices most accurately describes the splitting of the *d* orbitals in a linear crystal field? [Section 23.6]

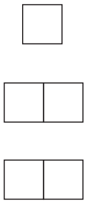




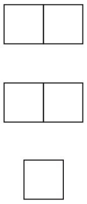
(a)



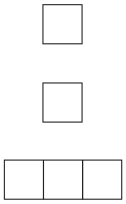
(b)



(c)



(d)



(e)

23.10 Two Fe(II) complexes are both low spin but have different ligands. A solution of one is green and a solution of the other is red. Which solution is likely to contain the complex that has the stronger-field ligand? [Section 23.6]

The Transition Metals (Section 23.1)

23.11 The lanthanide contraction explains which of the following periodic trends? (**a**) The atomic radii of the transition metals first decrease and then increase when moving horizontally across each period. (**b**) When forming ions, the period 4 transition metals lose their 4*s* electrons before their 3*d* electrons. (**c**) The radii of the period 5 transition metals (Y–Cd) are very similar to the radii of the period 6 transition metals (Lu–Hg).

23.12 Which periodic trend is partially responsible for the observation that the maximum oxidation state of the transition-metal elements peaks near groups 7B and 8B? (**a**) The number of valence electrons reaches a maximum at group 8B. (**b**) The effective nuclear charge increases on moving left across each period. (**c**) The radii of the transition-metal elements reach a minimum for group 8B, and as the size of the atoms decreases it becomes easier to remove electrons.

23.13 For each of the following compounds, determine the electron configuration of the transition-metal ion: (**a**) TiO, (**b**) TiO_2, (**c**) NiO, (**d**) ZnO.

23.14 Among the period 4 transition metals (Sc–Zn), which elements do *not* form ions where there are partially filled 3*d* orbitals?

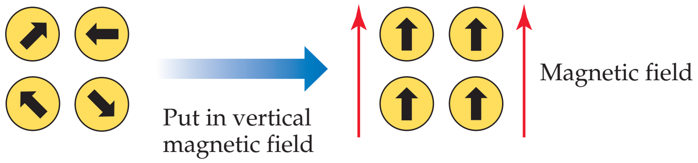
23.15 Write out the ground-state electron configurations of (**a**) Ti^{3+}, (**b**) Ru^{2+}, (**c**) Au^{3+}, (**d**) Mn^{4+}.

23.16 How many electrons are in the valence *d* orbitals in these transition-metal ions? (**a**) Co^{3+} (**b**) Cu^{+} (**c**) Cd^{2+} (**d**) Os^{3+}

23.17 Which type of substance is attracted by a magnetic field, a diamagnetic substance or a paramagnetic substance?

23.18 Which type of magnetic material cannot be used to make permanent magnets, a ferromagnetic substance, an antiferromagnetic substance, or a ferrimagnetic substance?

23.19 What kind of magnetism is exhibited by the following diagram?



23.20 The most important oxides of iron are magnetite, Fe_3O_4, and hematite, Fe_2O_3. (**a**) What are the oxidation states of iron in these compounds? (**b**) One of these iron oxides is ferrimagnetic, and the other is antiferromagnetic. Which iron oxide is more likely to be ferrimagnetic? Explain.

Transition-Metal Complexes (Section 23.2)

23.21 (**a**) Using Werner's definition of valence, which property is the same as oxidation number, *primary valence* or *secondary valence*? (**b**) What term do we normally use for the other type of valence? (**c**) Why can NH_3 serve as a ligand but BH_3 cannot?

23.22 Which species are more likely to act as ligands? (**a**) Positively charged ions or negatively charged ions (**b**) Neutral molecules that are polar or those that are nonpolar

23.23 A complex is written as $NiBr_2 \cdot 6\,NH_3$. (**a**) What is the oxidation state of the Ni atom in this complex? (**b**) What is the likely coordination number for the complex? (**c**) If the complex is treated with excess $AgNO_3(aq)$, how many moles of AgBr will precipitate per mole of complex?

23.24 Crystals of hydrated chromium(III) chloride are green, have an empirical formula of $CrCl_3 \cdot 6\,H_2O$, and are highly soluble, (**a**) Write the complex ion that exists in this compound. (**b**) If the complex is treated with excess $AgNO_3(aq)$, how many moles of AgCl will precipitate per mole of $CrCl_3 \cdot 6\,H_2O$ dissolved in solution? (**c**) Crystals of anhydrous chromium(III) chloride are violet and insoluble in aqueous solution. The coordination geometry of chromium in these crystals is octahedral, as is almost always the case for Cr^{3+}. How can this be the case if the ratio of Cr to Cl is not 1:6?

23.25 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:

(**a**) $Na_2[CdCl_4]$

(**b**) $K_2[MoOCl_4]$

(**c**) $[Co(NH_3)_4Cl_2]Cl$

(**d**) $[Ni(CN)_5]^{3-}$

(**e**) $K_3[V(C_2O_4)_3]$

(**f**) $[Zn(en)_2]Br_2$

23.26 Indicate the coordination number and the oxidation number of the metal for each of the following complexes:

(**a**) $K_3[Co(CN)_6]$

(**b**) $Na_2[CdBr_4]$

(**c**) $[Pt(en)_3](ClO_4)_4$

(**d**) $[Co(en)_2(C_2O_4)]^{+}$

(**e**) $NH_4[Cr(NH_3)_2(NCS)_4]$

(**f**) $[Cu(bipy)_2I]I$

Common Ligands in Coordination Chemistry (Section 23.3)

23.27 For each of the following molecules or polyatomic ions, draw the Lewis structure and indicate if it can act as a monodentate ligand or a bidentate ligand, or is unlikely to act as a ligand at all: (**a**) ethylamine, $CH_3CH_2NH_2$, (**b**) trimethylphosphine, $P(CH_3)_3$, (**c**) carbonate, $CO_3{}^{2-}$, (**d**) ethane, C_2H_6.

23.28 For each of the following polydentate ligands, determine (i) the maximum number of coordination sites that the ligand can occupy on a single metal ion, and (ii) the number and type of donor atoms in the ligand: (**a**) ethylenediamine (en), (**b**) bipyridine (bipy), (**c**) the oxalate anion $(C_2O_4{}^{2-})$, (**d**) the 2− ion of the porphine molecule (Figure 23.13), (**e**) $[EDTA]^{4-}$.

23.29 Polydentate ligands can vary in the number of coordination positions they occupy. In each of the following, identify the polydentate ligand present and indicate the probable number of coordination positions it occupies:

(**a**) $[Co(NH_3)_4(o\text{-phen})]Cl_3$

(**b**) $[Cr(C_2O_4)(H_2O)_4]Br$

(**c**) $[Ca(EDTA)]^{2-}$

(**d**) $[Zn(en)_2](ClO_4)_2$

23.30 Indicate the likely coordination number of the metal in each of the following complexes:

(a) $[Rh(bipy)_3](NO_3)_3$

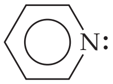
(b) $Na_3[Co(C_2O_4)_2Cl_2]$

(c) $[Cr(o\text{-}phen)_3](CH_3COO)_3$

(d) $Na_2[Co(EDTA)Br]$

23.31 For each of the following pairs, identify the molecule or ion that is more likely to act as a ligand in a metal complex: (**a**) acetonitrile (CH_3CN) or ammonium (NH_4^+), (**b**) hydride (H^-) or hydronium (H_3O^+), (**c**) carbon monoxide (CO) or methane (CH_4).

23.32 Pyridine (C_5H_5N), abbreviated py, is the molecule

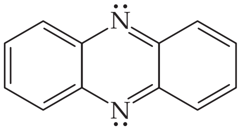


(**a**) Would you expect pyridine to act as a monodentate or bidentate ligand? (**b**) For the equilibrium reaction

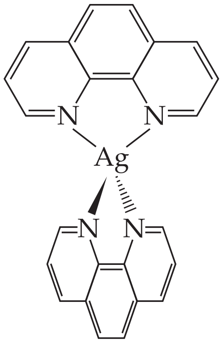
$$[Ru(py)_4(bipy)]^{2+} + 2\,py \rightleftharpoons [Ru(py)_6]^{2+} + bipy$$

would you predict the equilibrium constant to be larger or smaller than one?

23.33 *True* or *false*? The following ligand can act as a bidentate ligand?



23.34 When silver nitrate is reacted with the molecular base *ortho*-phenanthroline, colorless crystals form that contain the transition-metal complex shown here. (**a**) What is the coordination geometry of silver in this complex? (**b**) Assuming no oxidation or reduction occurs during the reaction, what is charge of the complex shown here? (**c**) Do you expect that any nitrate ions will be present in the crystal? (**d**) Write a formula for the compound that forms in this reaction. (**e**) Use the accepted nomenclature to write the name of this compound.



Nomenclature and Isomerism in Coordination Chemistry (Section 23.4)

23.35 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
(**a**) hexaamminechromium(III) nitrate
(**b**) tetraamminecarbonatocobalt(III) sulfate
(**c**) dichlorobis(ethylenediamine)platinum(IV) bromide
(**d**) potassium diaquatetrabromovanadate(III)
(**e**) bis(ethylenediamine)zinc(II) tetraiodomercurate(II)

23.36 Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
(**a**) tetraaquadibromomanganese(III) perchlorate
(**b**) bis(bipyridyl)cadmium(II) chloride
(**c**) potassium tetrabromo(*ortho*-phenanthroline)cobaltate(III)
(**d**) cesium diamminetetracyanochromate(III)
(**e**) tris(ethylenediamine)rhodium(III) tris(oxalato)cobaltate(III)

23.37 Write the names of the following compounds, using the standard nomenclature rules for coordination complexes:

(**a**) $[Rh(NH_3)_4Cl_2]Cl$

(**b**) $K_2[TiCl_6]$

(**c**) $MoOCl_4$

(**d**) $[Pt(H_2O)_4(C_2O_4)]Br_2$

23.38 Write the names of the following coordination compounds:

(**a**) $[Cd(en)Cl_2]$

(**b**) $K_4[Mn(CN)_6]$

(**c**) $[Cr(NH_3)_5(CO_3)]Cl$

(**d**) $[Ir(NH_3)_4(H_2O)_2](NO_3)_3$

23.39 Consider the following three complexes:
(Complex 1) $[Co(NH_3)_4Br_2]Cl$
(Complex 2) $[Pd(NH_3)_2(ONO)_2]$
(Complex 3) $[V(en)_2Cl_2]^+$,
Which of the three complexes can have (**a**) geometric isomers, (**b**) linkage isomers, (**c**) optical isomers, (**d**) coordination-sphere isomers?

23.40 Consider the following three complexes:
(Complex 1) $[Co(NH_3)_5SCN]^{2+}$
(Complex 2) $[Co(NH_3)_3Cl_3]^{2+}$
(Complex 3) $CoClBr \cdot 5NH_3$
Which of the three complexes can have (**a**) geometric isomers, (**b**) linkage isomers, (**c**) optical isomers, (**d**) coordination-sphere isomers?

23.41 A four-coordinate complex MA_2B_2 is prepared and found to have two different isomers. Is it possible to determine from this information whether the complex is square planar or tetrahedral? If so, which is it?

23.42 Consider an octahedral complex MA_3B_3. How many geometric isomers are expected for this compound? Will any of the isomers be optically active? If so, which ones?

23.43 Determine if each of the following complexes exhibits geometric isomerism. If geometric isomers exist, determine how many there are. (**a**) tetrahedral $[Cd(H_2O)_2Cl_2]$, (**b**) square-planar $[IrCl_2(PH_3)_2]^-$, (**c**) octahedral $[Fe(o\text{-}phen)_2Cl_2]^+$.

23.44 Determine if each of the following complexes exhibits geometric isomerism. If geometric isomers exist, determine how many there are. (**a**) $[Rh(\mathit{bipy})(o\text{-}phen)_2]^{3+}$, (**b**) $[Co(NH_3)_3(bipy)Br]^{2+}$, (**c**) square-planar $[Pd(en)(CN)_2]$.

23.45 Determine if each of the following metal complexes is chiral and therefore has an optical isomer: (**a**) tetrahedral $[Zn(H_2O)_2Cl_2]$, (**b**) octahedral *trans*-$[Ru(bipy)_2Cl_2]$, (**c**) octahedral *cis*-$[Ru(bipy)_2Cl_2]$.

23.46 Determine if each of the following metal complexes is chiral and therefore has an optical isomer: (**a**) square-planar $[Pd(en)(CN)_2]$, (**b**) octahedral $[Ni(en)(NH_3)_4]^{2+}$, (**c**) octahedral *cis*-$[V(en)_2ClBr]$.

Color and Magnetism in Coordination Chemistry; Crystal-Field Theory (Sections 23.5 and 23.6)

23.47 (**a**) If a complex absorbs light at 610 nm, what color would you expect the complex to be? (**b**) What is the energy in joules of a photon with a wavelength of 610 nm? (**c**) What is the energy of this absorption in kJ/mol?

23.48 (**a**) A complex absorbs photons with an energy of 4.51×10^{-19} J. What is the wavelength of these photons? (**b**) If this is the only place in the visible spectrum where the complex absorbs light, what color would you expect the complex to be?

23.49 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:

(**a**) $[ZnCl_4]^{2-}$

(**b**) $[Pd(NH_3)_2Cl_2]$

(**c**) $[V(H_2O)_6]^{3+}$

(**d**) $[Ni(en)_3]^{2+}$

23.50 Identify each of the following coordination complexes as either diamagnetic or paramagnetic:

(**a**) $[Ag(NH_3)_2]^+$

(**b**) square-planar $[Cu(NH_3)_4]^{2+}$

(**c**) $[Ru(bipy)_3]^{2+}$

(**d**) $[CoCl_4]^{2-}$

23.51 If the lobes of a given *d* orbital point directly at the ligands, will an electron in that orbital have a higher or lower energy than an electron in a *d* orbital whose lobes *do not* point directly at the ligands?

23.52 The lobes of which *d* orbitals point directly between the ligands in (**a**) octahedral geometry, (**b**) tetrahedral geometry?

23.53 (**a**) Sketch a diagram that shows the definition of the *crystal-field splitting energy* (Δ) for an octahedral crystal field. (**b**) What is the relationship between the magnitude of Δ and the energy of the *d–d* transition for a d^1 complex? (**c**) Calculate Δ in kJ/mol if a d^1 complex has an absorption maximum at 545 nm.

23.54 As shown in Figure 23.26, the *d–d* transition of $[Ti(H_2O)_6]^{3+}$ produces an absorption maximum at a wavelength of about 500 nm. (**a**) What is the magnitude of Δ for $[Ti(H_2O)_6]^{3+}$ in kJ/mol? (**b**) How would the magnitude of Δ change if the H_2O ligands in $[Ti(H_2O)_6]^{3+}$ were replaced with NH_3 ligands?

23.55 The colors in the copper-containing minerals malachite, which is green and has an empirical formula of $Cu_2CO_3(OH)_2$, and azurite, which is blue and has an empirical formula of $Cu_3(CO_3)_2(OH)_2$, come from a single *d–d* transition in each compound. The compounds are sometimes found together in nature as shown in Figure 23.1. (**a**) What is the electron configuration of the copper ion in each mineral? (**b**) Based on their colors, in which compound would you predict the crystal-field splitting Δ is larger?

23.56 The color and wavelength of the absorption maximum for $[Ni(H_2O)_6]^{2+}$, $[Ni(NH_3)_6]^{2+}$, and $[Ni(en)_3]^{2+}$ are given in Figure 23.30. The absorption maximum for the $[Ni(bipy)_3]^{2+}$ ion occurs at about 520 nm. (**a**) What color would you expect for the $[Ni(bipy)_3]^{2+}$ ion? (**b**) Based on these data, where would you put bipy in the spectrochemical series?

23.57 Give the number of (valence) *d* electrons associated with the central metal ion in each of the following complexes: (**a**) $K_3[TiCl_6]$, (**b**) $Na_3[Co(NO_2)_6]$, (**c**) $[Ru(en)_3]Br_3$, (**d**) $[Mo(EDTA)]ClO_4$, (**e**) $K_3[ReCl_6]$.

23.58 Give the number of (valence) *d* electrons associated with the central metal ion in each of the following complexes: (**a**) $K_3[Fe(CN)_6]$, (**b**) $[Mn(H_2O)_6](NO_3)_2$, (**c**) $Na[Ag(CN)_2]$, (**d**) $[Cr(NH_3)_4Br_2]ClO_4$, (**e**) $[Sr(EDTA)]^{2-}$.

23.59 A classmate says, “A weak-field ligand usually means the complex is high spin.” Is your classmate correct? Explain.

23.60 For a given metal ion and set of ligands, is the crystal-field splitting energy larger for a tetrahedral or an octahedral geometry?

23.61 For each of the following metals, write the electronic configuration of the atom and its 2+ ion: (**a**) Mn, (**b**) Ru, (**c**) Rh. Draw the crystal-field energy-level diagram for the *d* orbitals of an octahedral complex, and show the placement of the *d* electrons for each 2+ ion, assuming a strong-field complex. How many unpaired electrons are there in each case?

23.62 For each of the following metals, write the electronic configuration of the atom and its 3+ ion: (**a**) Fe, (**b**) Mo, (**c**) Co. Draw the crystal-field energy-level diagram for the *d* orbitals of an octahedral complex, and show the placement of the *d* electrons for each 3+ ion, assuming a weak-field complex. How many unpaired electrons are there in each case?

23.63 Draw the crystal-field energy-level diagrams and show the placement of *d* electrons for each of the following: (**a**) $[Cr(H_2O)_6]^{2+}$ (four unpaired electrons), (**b**) $[Mn(H_2O)_6]^{2+}$ (a high-spin complex), (**c**) $[Ru(NH_3)_5(H_2O)]^{2+}$ (a low-spin complex), (**d**) $[IrCl_6]^{2-}$ (a low-spin complex), (**e**) $[Cr(en)_3]^{3+}$, (**f**) $[NiF_6]^{4-}$.

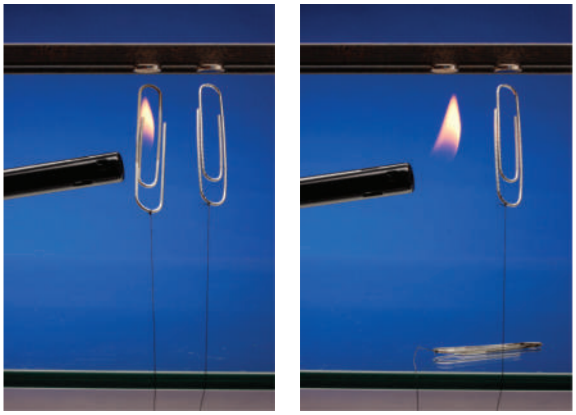
23.64 Draw the crystal-field energy-level diagrams and show the placement of electrons for the following complexes: (**a**) $[VCl_6]^{3-}$, (**b**) $[FeF_6]^{3-}$ (a high-spin complex), (**c**) $[Ru(bipy)_3]^{3+}$ (a low-spin complex), (**d**) $[NiCl_4]^{2-}$ (tetrahedral), (**e**) $[PtBr_6]^{2-}$, (**f**) $[Ti(en)_3]^{2+}$.

23.65 The complex $[Mn(NH_3)_6]^{2+}$ contains five unpaired electrons. Sketch the energy-level diagram for the *d* orbitals, and indicate the placement of electrons for this complex ion. Is the ion a high-spin or a low-spin complex?

23.66 The ion $[Fe(CN)_6]^{3-}$ has one unpaired electron, whereas $[Fe(NCS)_6]^{3-}$ has five unpaired electrons. From these results, what can you conclude about whether each complex is high spin or low spin? What can you say about the placement of NCS^- in the spectrochemical series?

Additional Exercises

23.67 The *Curie temperature* is the temperature at which a ferromagnetic solid switches from ferromagnetic to paramagnetic. For nickel, the Curie temperature is 354 °C. Knowing this, you tie a string to two paper clips made of nickel and hold the paper clips near a permanent magnet. The magnet attracts the paper clips, as shown in the photograph on the left. Now you heat one of the paper clips with a butane lighter, and the clip drops (right photograph). Explain what happened.



23.68 Explain why the transition metals in periods 5 and 6 have nearly identical radii in each group.

23.69 Based on the molar conductance values listed here for the series of platinum(IV) complexes, write the formula for each complex so as to show which ligands are in the coordination sphere of the metal. By way of example, the molar conductances of 0.050 *M* NaCl and $BaCl_2$ are 107 ohm^{-1} and 197 ohm^{-1}, respectively.

Complex	Molar Conductance (ohm^{-1})* of 0.050 *M* Solution
$Pt(NH_3)_6Cl_4$	523
$Pt(NH_3)_4Cl_4$	228
$Pt(NH_3)_3Cl_4$	97
$Pt(NH_3)_2Cl_4$	0
$KPt(NH_3)Cl_5$	108

*The ohm is a unit of resistance; conductance is the inverse of resistance.

23.70 (**a**) A compound with formula $RuCl_3 \cdot 5\,H_2O$ is dissolved in water, forming a solution that is approximately the same color as the solid. Immediately after forming the solution, the addition of excess $AgNO_3(aq)$ forms 2 mol of solid AgCl per mole of complex. Write the formula for the compound, showing which ligands are likely to be present in the coordination sphere. (**b**) After a solution of $RuCl_3 \cdot 5\,H_2O$ has stood for about a year, addition of $AgNO_3(aq)$ precipitates 3 mol of AgCl per mole of complex. What has happened in the ensuing time?

23.71 Sketch the structure of the complex in each of the following compounds and give the full compound name:

(**a**) *cis*-$[Co(NH_3)_4(H_2O)_2](NO_3)_2$

(**b**) $Na_2[Ru(H_2O)Cl_5]$

(**c**) *trans*-$NH_4[Co(C_2O_4)_2(H_2O)_2]$

(**d**) *cis*-$[Ru(en)_2Cl_2]$

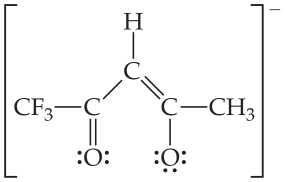
23.72 Which complex ions in Exercise 23.71 have optical isomers?

23.73 The molecule *dimethylphosphinoethane* [$(CH_3)_2PCH_2CH_2P(CH_3)_2$, which is abbreviated dmpe] is used as a ligand for some complexes that serve as catalysts. An octahedral complex that contains this ligand is $Mo(CO)_4(dmpe)$. (**a**) Draw the Lewis structure for dmpe. (**b**) Is dmpe a monodentate, bidentate, or polydentate ligand? (**c**) What is the oxidation state of Mo in $Mo(CO)_4(dmpe)$? (**d**) Is $Mo(CO)_4(dmpe)$ a chiral molecule?

23.74 The square-planar complex $[Pt(en)Cl_2]$ only forms in one of two possible geometric isomers. Which isomer is not observed: cis or trans?

23.75 The acetylacetone ion forms very stable complexes with many metallic ions. It acts as a bidentate ligand, coordinating to the metal at two adjacent positions. Suppose that one of the CH_3 groups of the ligand is replaced by a CF_3 group, as shown here:

Trifluoromethyl
acetylacetonate
(tfac)



Sketch all possible isomers for the complex with three tfac ligands on cobalt(III). (You can use the symbol ●◌ to represent the ligand.)

23.76 Which transition-metal atom is present in each of the following biologically important molecules: (**a**) hemoglobin, (**b**) chlorophylls, (**c**) siderophores, (**d**) hemocyanine.

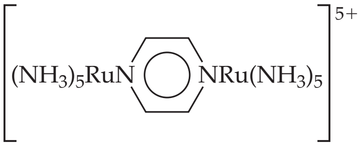
23.77 Carbon monoxide, CO, is an important ligand in coordination chemistry. When CO is reacted with nickel metal, the product is $[Ni(CO)_4]$, which is a toxic, pale yellow liquid. (**a**) What is the oxidation number for nickel in this compound? (**b**) Given that $[Ni(CO)_4]$ is a diamagnetic molecule with a tetrahedral geometry, what is the electron configuration of nickel in this compound? (**c**) Write the name for $[Ni(CO)_4]$ using the nomenclature rules for coordination compounds.

23.78 Some metal complexes have a coordination number of 5. One such complex is $Fe(CO)_5$, which adopts a *trigonal-bipyramidal* geometry (see Figure 9.8). (**a**) Write the name for $Fe(CO)_5$, using the nomenclature rules for coordination compounds. (**b**) What is the oxidation state of Fe in this compound? (**c**) Suppose one of the CO ligands is replaced with a CN^- ligand, forming $[Fe(CO)_4(CN)]^-$. How many geometric isomers would you predict this complex could have?

23.79 Which of the following objects is chiral? (**a**) a left shoe (**b**) a slice of bread (**c**) a wood screw (**d**) a molecular model of $Zn(en)Cl_2$ (**e**) a typical golf club

23.80 The complexes $[V(H_2O)_6]^{3+}$ and $[VF_6]^{3-}$ are both known. (**a**) Draw the *d*-orbital energy-level diagram for V(III) octahedral complexes. (**b**) Which of the following gives rise to the colors of these complexes? (**i**) Excitation of an electron from the *e* orbitals to the t_2 orbitals. (**ii**) Excitation of an electron from the t_2 orbitals to the *e* orbitals. (**iii**) Excitation of a 4*s* electron to the t_2 orbitals. (**c**) Which of the two complexes would you expect to absorb light of higher energy?

23.81 One of the more famous species in coordination chemistry is the Creutz–Taube complex, discovered in 1969:



It is named for Carol Creutz and 1983 Chemistry Nobel Laureate Henry Taube, the two scientists who discovered, it and initially studied its properties. The central ligand is pyrazine, a planar six-membered ring with nitrogens at opposite sides. (**a**) How can you account for the fact that the complex, which has only neutral ligands, has an odd overall charge? (**b**) The metal is in a low-spin configuration in both cases. Assuming octahedral coordination, draw the *d*-orbital energy-level diagram for each metal. (**c**) In many experiments, the two metal ions appear to be in exactly equivalent states. Can you think of a reason that this might appear to be so, recognizing that electrons move very rapidly compared to nuclei?

23.82 Solutions of $[Co(NH_3)_6]^{2+}$, $[Co(H_2O)_6]^{2+}$ (both octahedral), and $[CoCl_4]^{2-}$ (tetrahedral) are colored. One is pink, one is blue, and one is yellow. Based on the spectrochemical series and remembering that the energy splitting in tetrahedral complexes is normally much less than that in octahedral ones, assign a color to each complex.

23.83 Oxyhemoglobin, with an O_2 bound to iron, is a low-spin Fe(II) complex; deoxyhemoglobin, without the O_2 molecule, is a high-spin complex. (**a**) Assuming that the coordination environment about the metal is octahedral, how many unpaired electrons are centered on the metal ion in each case? (**b**) What ligand is coordinated to the iron in place of O_2 in deoxyhemoglobin? (**c**) Explain in a general way why the two forms of hemoglobin have different colors (hemoglobin is red, whereas deoxyhemoglobin has a bluish cast). (**d**) A 15-minute exposure to air containing 400 ppm of CO causes about 10% of the hemoglobin in the blood to be converted into the carbon monoxide complex called carboxyhemoglobin. What does this suggest about the relative equilibrium constants for binding of carbon monoxide and O_2 to hemoglobin? (**e**) CO is a strong-field ligand. What color might you expect carboxyhemoglobin to be?

23.84 Consider the tetrahedral anions VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^{-} (permanganate ion). (**a**) These anions are *isoelectronic*. What does this statement mean? (**b**) Would you expect these anions to exhibit *d–d* transitions? Explain. (**c**) As mentioned in the "A Closer Look" box on "Charge-Transfer Color" (Section 23.6), the violet color of MnO_4^{-} is due to a *ligand-to-metal charge transfer* (LMCT) transition. What is meant by this term? (**d**) The LMCT transition in MnO_4^{-} occurs at a wavelength of 565 nm. The CrO_4^{2-} ion is yellow. Is the wavelength of the LMCT transition for chromate larger or smaller than that for MnO_4^{-}? Explain. (**e**) The VO_4^{3-} ion is colorless. Do you expect the light absorbed by the LMCT to fall in the UV or the IR region of the electromagnetic spectrum? Explain your reasoning.

23.85 Given the colors observed for VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^{-} (permanganate ion) (see Exercise 23.84), what can you say about how the energy separation between the ligand orbitals and the empty *d* orbitals changes as a function of the oxidation state of the transition metal at the center of the tetrahedral anion?

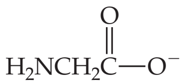
23.86 The red color of ruby is due to the presence of Cr(III) ions at octahedral sites in the close-packed oxide lattice of Al_2O_3. Draw the crystal-field splitting diagram for Cr(III) in this environment. Suppose that the ruby crystal is subjected to high pressure. What do you predict for the variation in the wavelength of absorption of the ruby as a function of pressure? Explain.

23.87 In 2001, chemists at SUNY-Stony Brook succeeded in synthesizing the complex *trans*-$[Fe(CN)_4(CO)_2]^{2-}$, which could be a model of complexes that may have played a role in the origin of life. (**a**) Sketch the structure of the complex. (**b**) The complex is isolated as a sodium salt. Write the complete name of this salt. (**c**) What is the oxidation state of Fe in this complex? How many *d* electrons are associated with the Fe in this complex? (**d**) Would you expect this complex to be high spin or low spin? Explain.

23.88 When Alfred Werner was developing the field of coordination chemistry, it was argued by some that the optical activity he observed in the chiral complexes he had prepared was due to the presence of carbon atoms in the molecule. To disprove this argument, Werner synthesized a chiral complex of cobalt that had no carbon atoms in it, and he was able to resolve it into its enantiomers. Design a cobalt(III) complex that would be chiral if it could be synthesized and that contains no carbon atoms. (It may not be possible to synthesize the complex you design, but we will not worry about that for now.)

23.89 Generally speaking, for a given metal and ligand, the stability of a coordination compound is greater for the metal in the +3 rather than in the +2 oxidation state (for metals that form stable +3 ions in the first place). Suggest an explanation, keeping in mind the Lewis acid–base nature of the metal–ligand bond.

23.90 Many trace metal ions exist in the blood complexed with amino acids or small peptides. The anion of the amino acid glycine (gly),



$$H_2NCH_2\overset{\overset{\displaystyle O}{\|}}{C}-O^-$$

can act as a bidentate ligand, coordinating to the metal through nitrogen and oxygen atoms. How many isomers are possible for (**a**) $[Zn(gly)_2]$ (tetrahedral), (**b**) $[Pt(gly)_2]$ (square planar), (**c**) $[Co(gly)_3]$ (octahedral)? Sketch all possible isomers. Use the symbol ●◠○ to represent the ligand.

23.91 The coordination complex $[Cr(CO)_6]$ forms colorless, diamagnetic crystals that melt at 90 °C. (**a**) What is the oxidation number of chromium in this compound? (**b**) Given that $[Cr(CO)_6]$ is diamagnetic, what is the electron configuration of chromium in this compound? (**c**) Given that $[Cr(CO)_6]$ is colorless, would you expect CO to be a weak-field or strong-field ligand? (**d**) Write the name for $[Cr(CO)_6]$ using the nomenclature rules for coordination compounds.

23.92 Metallic elements are essential components of many important enzymes operating within our bodies. *Carbonic anhydrase*, which contains Zn^{2+} in its active site, is responsible for rapidly interconverting dissolved CO_2 and bicarbonate ion, HCO_3^{-}. The zinc in carbonic anhydrase is tetrahedrally coordinated by three neutral nitrogen-containing groups and a water molecule. The coordinated water molecule has a pK_a of 7.5, which is crucial for the enzyme's activity. (**a**) Draw the active site geometry for the Zn(II) center in carbonic anhydrase, just writing "N" for the three neutral nitrogen ligands from the protein. (**b**) Compare the pK_a of carbonic anhydrase's active site with that of pure water; which species is more acidic? (**c**) When the coordinated water to the Zn(II) center in carbonic anhydrase is deprotonated, what ligands are bound to the Zn(II) center? Assume the three nitrogen ligands are unaffected. (**d**) The pK_a of $[Zn(H_2O)_6]^{2+}$ is 10. Suggest an explanation for the difference between this pK_a and that of carbonic anhydrase. (**e**) Would you expect carbonic anhydrase to have a deep color, like hemoglobin and other metal-ion-containing proteins do? Explain.

23.93 Two different compounds have the formulation $CoBr(SO_4) \cdot 5\,NH_3$. Compound A is dark violet, whereas compound B is red-violet. When compound A is treated with $AgNO_3(aq)$, no reaction occurs, whereas compound B reacts with $AgNO_3(aq)$ to form a white precipitate. When compound A is treated with $BaCl_2(aq)$, a white precipitate is formed, whereas compound B has no reaction with $BaCl_2(aq)$. (**a**) Is Co in the same oxidation state in these complexes? (**b**) What substance precipitates when compound B reacts with $AgNO_3(aq)$? (**c**) What substance precipitates when compound A reacts with $BaCl_2(aq)$? (**d**) Are compounds A and B isomers of one another? If so, which category from Figure 23.19 best describes the isomerism observed for these complexes? (**e**) Would compounds A and B be expected to be strong electrolytes, weak electrolytes, or nonelectrolytes?

23.94 The value of Δ for the $[CrF_6]^{3-}$ complex is 182 kJ/mol. Calculate the expected wavelength of the absorption corresponding to promotion of an electron from the lower-energy to the higher-energy *d*-orbital set in this complex. Should the complex absorb in the visible range?

Design an Experiment

Following a procedure found in a scientific paper, you go into the lab and attempt to prepare crystals of dichlorobis(ethylenediamine) cobalt(III) chloride. The paper states that this compound can be made by reacting $CoCl_2 \cdot 6\,H_2O$, an excess of ethylenediamine, O_2 from the air (which acts as an oxidizing agent), water, and concentrated hydrochloric acid. At the end of the reaction, you filter off the solution and are left with a green, crystalline product. (**a**) What experiment(s) could you perform to confirm that you have prepared $[CoCl_2(en)_2]Cl$ and not $[Co(en)_3]Cl_3$? (**b**) How could you verify that cobalt was present as Co^{3+} and determine the spin state of the cobalt complex in your product? (**c**) How many geometric isomers exist for $[CoCl_2(en)_2]Cl$? How could you determine if your product contains a single geometric isomer or a mixture of geometric isomers? (**d**) If the product does contain a single geometric isomer, how would you determine which one was present? (*Hint:* You may find the information in Table 23.3 to be helpful.)

THE CHEMISTRY OF LIFE: ORGANIC AND BIOLOGICAL CHEMISTRY

▲ **SPICE MARKET.** The many colors and tastes of these spices come from the organic compounds they contain.

Chemical substances can influence our health and behavior. Aspirin, also known as acetylsalicylic acid, relieves aches and pains. The caffeine that is in coffee and tea, and the ethanol that is in wine and beer, are well-known molecules that at the proper doses give us pleasure. Spices, as shown in the opening photograph, contain a host of molecules such as capsaicin (in chili peppers), cinnamaldehyde (in cinnamon), and vanillin (in the vanilla bean). Other plant-derived compounds include quinine, for treating malaria, and taxol, for treating many kinds of cancer.

Understanding how these molecules exert their effects and developing new molecules that can target disease and pain are important components of the modern chemical enterprise. This chapter is about the molecules, composed mainly of carbon, hydrogen, oxygen, and nitrogen, that bridge chemistry and biology.

More than 16 million carbon-containing compounds are known. The study of compounds whose molecules contain carbon constitutes the branch of chemistry known as **organic chemistry**. This term arose from the eighteenth-century belief that organic compounds could be formed only by living (that is, organic) systems. This idea was disproved by the German chemist Friedrich Wöhler (1800–1882). In 1828, he

WHAT'S AHEAD

24.1 ▶ General Characteristics of Organic Molecules Review the structures and properties of organic compounds.

24.2 ▶ Introduction to Hydrocarbons Consider *hydrocarbons*, compounds containing only C and H, including the hydrocarbons called *alkanes*, which contain only single C—C bonds. We also look at *isomers*, compounds with identical compositions but different molecular structures.

24.3 ▶ Alkenes, Alkynes, and Aromatic Hydrocarbons Explore hydrocarbons with one or more C═C bonds, called *alkenes*, and those with one or more C≡C bonds, called *alkynes. Aromatic* hydrocarbons have at least one planar ring with delocalized π electrons.

24.4 ▶ Organic Functional Groups Recognize that a central organizing principle of organic chemistry is the *functional group*, a group of atoms at which most of the compound's chemical reactions occur.

24.5 ▶ Chirality in Organic Chemistry Learn that molecules with nonsuperimposable mirror images are *chiral* and that chirality plays important roles in organic and biological chemistry.

24.6 ▶ Proteins See that proteins are polymers of *amino acids* linked with *amide* (also called *peptide*) bonds. Proteins are used by organisms for structural support, as molecular transporters, and as catalysts for biochemical reactions.

24.7 ▶ Carbohydrates Explore the structures and properties of carbohydrates, a class of compounds that include sugars and polymers of sugars used primarily as fuel by organisms (glucose) or as structural support in plants (cellulose).

24.8 ▶ Lipids Understand that lipids are a large class of molecules used primarily for energy storage in organisms.

24.9 ▶ Nucleic Acids Learn that nucleic acids are polymers of *nucleotides* that contain an organism's genetic information. *Deoxyribonucleic acid* (DNA) and *ribonucleic acid* (RNA) are polymers composed of nucleotides.

synthesized urea (H_2NCONH_2), an organic substance found in the urine of mammals, by heating ammonium cyanate (NH_4OCN), an inorganic (nonliving) substance. In chemistry, "organic compounds" are typically considered to be those that contain carbon-hydrogen bonds. Therefore, compounds such as ammonia or carbon dioxide are generally considered "inorganic."

Although not all organic molecules are formed by living systems, the chemistry of plants, animals, and other living organisms is based on organic substances. The study of the chemistry of living species is called *biological chemistry*, *chemical biology*, or **biochemistry**. The molecules that play important roles in biology share some common characteristics. Many are large because organisms build biomolecules from smaller, simpler substances readily available in the biosphere. The synthesis of large molecules requires energy because most of the reactions are endothermic. The ultimate source of this energy is the Sun. Animals have essentially no capacity for using solar energy directly and so depend on plant photosynthesis to supply the bulk of their energy needs. (Section 23.3) In addition to requiring large amounts of energy, living organisms are highly organized. In thermodynamic terms, this high degree of organization means that the entropy of living systems is much lower than that of the raw materials from which the systems formed. Thus, living systems must continuously work against the spontaneous tendency toward increased entropy. (Section 19.3)

In the "Chemistry and Life" essays that appear throughout this text, we have introduced some important biochemical applications of fundamental chemical ideas. In the second half of this chapter we delve a little deeper into the composition, structure, and properties of biomolecules.

24.1 | General Characteristics of Organic Molecules

What is it about carbon that leads to the tremendous diversity in its compounds and allows it to play such crucial roles in biology and society? Let's start by considering some general features of organic molecules and, as we do, review principles we learned in previous chapters.

Learning Objectives

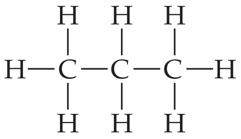
When you finish Section 24.1, you should be able to:

- Predict the molecular geometry, orbital hybridization, and pattern of bonding in organic molecules from their structural formulas.
- Predict the dipole moments and solubilities of organic compounds from their molecular structure.

The Structures of Organic Molecules

Because carbon has four valence electrons ($[\mathrm{He}]2s^22p^2$), it forms four bonds in virtually all its compounds. When all four bonds are single bonds, the electron pairs are disposed in a tetrahedral arrangement. (Section 9.2) In the hybridization model, the carbon $2s$ and $2p$ orbitals are then sp^3 hybridized. (Section 9.5) When there is one double bond, the geometry is trigonal planar and the orbitals at carbon are sp^2 hybridized. With a triple bond, the geometry is linear and the carbon is sp hybridized. Examples are shown in **Figure 24.1**.

Almost every organic molecule contains C—H bonds. Because the valence shell of H can hold only two electrons, hydrogen forms only one covalent bond. As a result, hydrogen atoms are always located on the *surface* of organic molecules, whereas the C—C bonds form the *backbone*, or *skeleton*, of the molecule, as in the propane molecule:

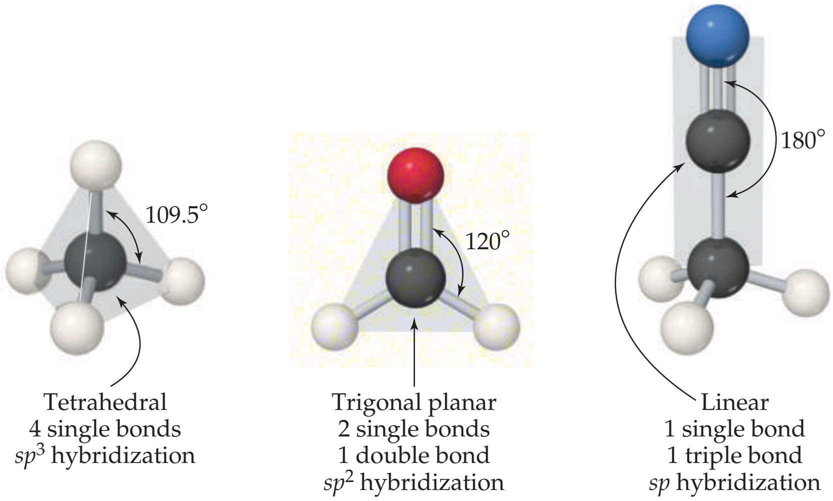


$$\begin{array}{ccccccc} & & \mathrm{H} & \mathrm{H} & \mathrm{H} & & \\ & & | & | & | & & \\ \mathrm{H} & — & \mathrm{C} — & \mathrm{C} — & \mathrm{C} & — & \mathrm{H} \\ & & | & | & | & & \\ & & \mathrm{H} & \mathrm{H} & \mathrm{H} & & \end{array}$$

The Stability of Organic Compounds

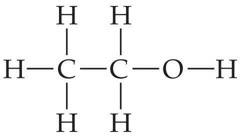
Carbon forms strong bonds with a variety of elements, especially H, O, N, and the halogens. (Sections 5.8 and 8.8) Carbon also has an exceptional ability to bond to itself, forming a variety of molecules made up of chains or rings of carbon atoms. Most reactions with low or moderate activation energy (Section 14.4) begin when a region of high-electron density in

Go Figure What is the geometry around the bottom carbon atom in acetonitrile?



▲ **Figure 24.1 Carbon geometries.** The three common geometries around carbon are tetrahedral as in methane (CH_4), trigonal planar as in formaldehyde (CH_2O), and linear as in acetonitrile (CH_3CN). Notice that in all cases each carbon atom forms four bonds.

one molecule encounters a region of low electron density in another molecule. The regions of high-electron density may be due to the presence of a multiple bond or to the more electronegative atom in a polar bond. Because of their strength (the C—C single bond enthalpy is 348 kJ/mol, and the C—H bond enthalpy is 413 kJ/mol (Tables 5.4 and 8.3) and lack of polarity, both C—C single bonds and C—H bonds are relatively unreactive. To better understand the implications of these facts, consider ethanol:



$$\begin{array}{ccccccccc} & & \mathrm{H} & & \mathrm{H} & & & & \\ & & | & & | & & & & \\ \mathrm{H} & — & \mathrm{C} & — & \mathrm{C} & — & \mathrm{O} & — & \mathrm{H} \\ & & | & & | & & & & \\ & & \mathrm{H} & & \mathrm{H} & & & & \end{array}$$

The differences in the electronegativity values of C (2.5), O (3.5) and H (2.1), indicate that the C—O and O—H bonds are quite polar. Thus, many reactions of ethanol involve these bonds while the hydrocarbon portion of the molecule remains intact. A group of atoms such as the C—O—H group, which determines how an organic molecule reacts (in other words, how the molecule *functions*), is called a **functional group**. The functional group is the center of reactivity in an organic molecule.

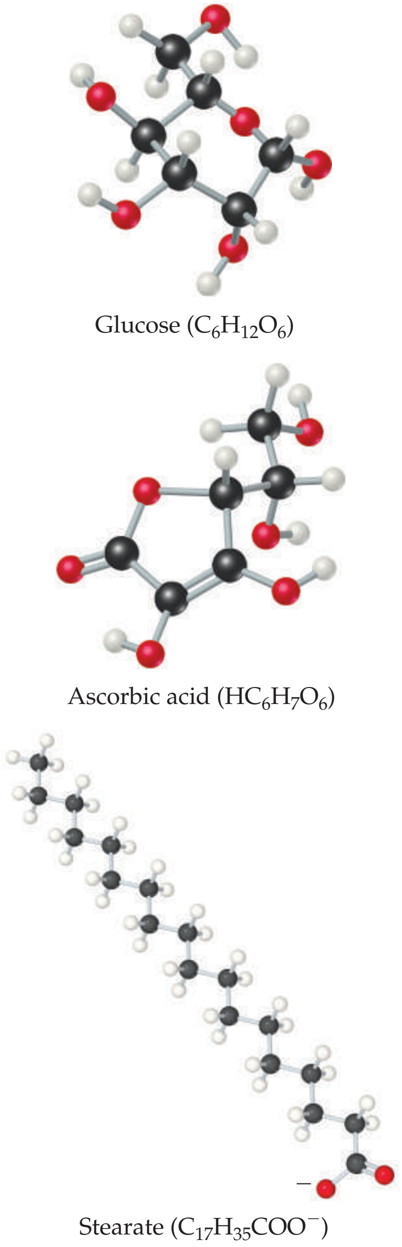
Solubility and Acid–Base Properties of Organic Compounds

In most organic substances, the nonpolar carbon–carbon and carbon–hydrogen bonds are most prevalent. For this reason, the overall polarity of organic molecules is often low, which makes them generally soluble in nonpolar solvents and not very soluble in water. (Section 13.3) Organic molecules that are soluble in polar solvents are those that have polar groups on the molecule surface, such as glucose and ascorbic acid (**Figure 24.2**). Organic molecules that have a long, nonpolar part bonded to a polar, ionic part, such as the stearate ion shown in Figure 24.2, function as *surfactants* and are used in soaps and detergents. (Section 13.6) The nonpolar part of the molecule extends into a nonpolar medium such as grease or oil, whereas the polar part extends into a polar medium such as water.

Many organic substances contain acidic or basic groups. The most important acidic organic substances are the carboxylic acids, which bear the functional group —COOH. (Sections 4.3 and 16.10) The most important basic organic substances are amines, which bear the $—NH_2$, —NHR, or $—NR_2$ groups, where R is an organic group made up of carbon and hydrogen atoms. (Section 16.7)

Go Figure

How would replacing OH groups on ascorbic acid with CH_3 groups affect the substance's solubility in (**a**) polar solvents and (**b**) nonpolar solvents?



Glucose ($C_6H_{12}O_6$)

24.2 | Introduction to Hydrocarbons

Learning Objectives

When you finish Section 24.2, you should be able to:

- Differentiate alkanes, alkenes, alkynes, and aromatic hydrocarbons from one another.
- Differentiate straight-chain alkanes, branched-chain alkanes, and cycloalkanes from one another.
- Interconvert between the structural formula of an alkane and its name.
- Identify alkanes that are structural isomers of each other.
- Write balanced chemical equations for the combustion of alkanes.

Because organic compounds are so numerous, it is convenient to organize them into families that have structural similarities. The simplest class of organic compounds, *hydrocarbons*, are composed of only carbon and hydrogen. Because carbon is the only element capable of forming stable, extended chains of atoms bonded through single, double, or triple bonds, the number of different substances that can be made from these two elements is surprisingly large.

Hydrocarbons can be divided into four types, depending on the kinds of carbon–carbon bonds in their molecules.

- **Alkanes** contain only single C—C bonds.
- **Alkenes**, also known as olefins, contain at least one C=C double bond.
- **Alkynes** contain at least one C≡C triple bond.
- **Aromatic hydrocarbons** have carbon atoms that are connected in a planar ring structure, joined by both σ and delocalized π bonds between carbon atoms. (Section 8.6)

An example of each type is shown in **Table 24.1**.

TABLE 24.1 The Four Hydrocarbon Types with Molecular Examples

Type	Example			
Alkane	Ethane	CH_3CH_3		Alkene	Ethene (ethylene)	$CH_2{=}CH_2$		Alkyne	Ethyne (acetylene)	$CH{\equiv}CH$		Aromatic	Benzene	C_6H_6		
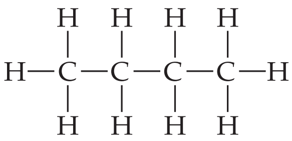
Each type of hydrocarbon exhibits different chemical behaviors, as we demonstrate shortly. The physical properties of all four types, however, are similar in many ways. Because hydrocarbon molecules are relatively nonpolar, they are almost completely insoluble in water but dissolve readily in nonpolar solvents. Their melting points and boiling points are determined by dispersion forces. (Section 11.2) As a result, hydrocarbons of very low molecular weight, such as C_2H_6 (bp = −89 °C), are gases at room temperature; those of moderate molecular weight, such as C_6H_{14} (bp = 69 °C), are liquids; and those of high molecular weight, such as $C_{22}H_{46}$ (mp = 44 °C), are solids.

The molecular formulas, names, and boiling points of simple alkanes were discussed in Chapter 2, as was the convention for naming them. To aid in understanding the material that follows, you should review Section 2.9.

Several alkanes may be familiar to you because they are so widely used. Methane (CH_4) is a major component of natural gas. Ethane (C_2H_6) is also a component of natural gas and is a feedstock for making polyethylene. (Section 12.6) Propane (C_3H_8) is the major component of bottled gas used for home heating and cooking in areas where natural gas is unavailable. Butane (C_4H_{10}) is used in disposable lighters and in fuel canisters for gas camping stoves and lanterns. Alkanes with 5 to 12 carbon atoms per molecule are components of gasoline.

The formulas for the alkanes are written in a notation called *condensed structural formulas*. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds. For example, the structural formula and the condensed structural formulas for butane (C_4H_{10}) are

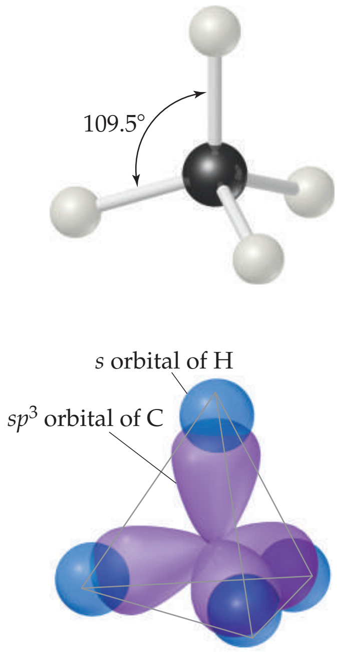


$$\begin{array}{ccccccccc} & & H & & H & & H & & H \\ & & | & & | & & | & & | \\ H & — & C & — & C & — & C & — & C & — H \\ & & | & & | & & | & & | \\ & & H & & H & & H & & H \end{array}$$

$$H_3C—CH_2—CH_2—CH_3$$

or

$$CH_3CH_2CH_2CH_3$$



▲ **Figure 24.3 Bonds about carbon in methane.** This tetrahedral molecular geometry is found around all carbon atoms in alkanes.

Structures of Alkanes

According to the VSEPR model, the molecular geometry about each carbon atom in an alkane is tetrahedral. (Section 9.2) The bonding may be described as involving sp^3-hybridized orbitals on the carbon, as pictured in **Figure 24.3** for methane. (Section 9.5)

Rotation about a carbon–carbon single bond is relatively easy and occurs rapidly at room temperature. To visualize such rotation, imagine grasping either methyl group of the propane molecule in **Figure 24.4** and rotating the group relative to the rest of the molecule. Because motion of this sort occurs rapidly in alkanes, a long-chain alkane molecule is constantly undergoing motions that cause it to change its overall shape.

Alkanes with more than three carbon atoms exhibit structural isomerism. (Sections 2.9 and 23.4) As an example, the three structural isomers of pentane are shown in **Figure 24.5**. Those molecules where the carbon atoms connected in a continuous chain, such as *n*-pentane (the letter *n* indicates this is the "normal" structure), are referred to as *straight-chain* or *linear hydrocarbons*. All other alkanes contain one or more side chains that come off the linear carbon backbone of the molecule and are referred to as *branched-chain hydrocarbons*, 2-methylbutane (isopentane) and 2,2-dimethylpropane (neopentane) are examples of branched-chain hydrocarbons. Both straight- and branched-chain alkanes have the same molecular formula, C_nH_{2n+2}, where n is the number of carbon atoms in the molecule. The structural isomers of a given alkane differ from one another in physical properties, as can be seen from the melting and boiling points of the pentane isomers. The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 isomers with the molecular formula C_8H_{18}, for example, and 75 with the molecular formula $C_{10}H_{22}$.

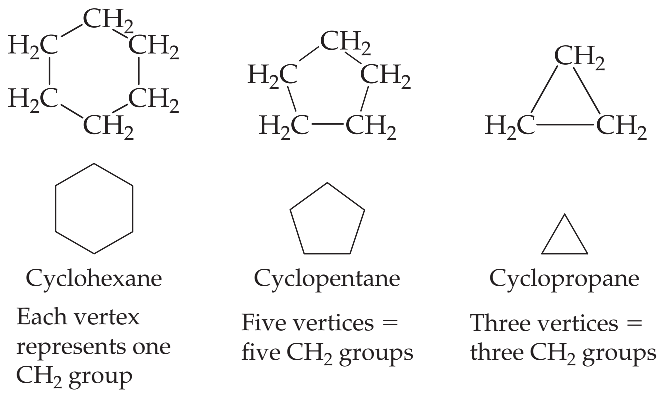
▲ **Figure 24.5 The three structural isomers of pentane C_5H_{12}.** In the straight-chain isomer, *n*-pentane, all five carbon atoms are connected in a continuous chain, while the other two isomers are branched-chain alkanes. The common names are given in blue below the systematic names for each compound. Rules for naming alkanes are described in Section 2.9. The physical and chemical properties of isomers differ from each other, as exemplified here by the melting points (mp) and boiling points (bp).

Go Figure The general formula for straight-chain alkanes is C_nH_{2n+2}. What is the general formula for cycloalkanes?



Cyclohexane
Each vertex represents one CH2 group
Cyclopentane
Five vertices = five CH2 groups
Cyclopropane
Three vertices = three CH2 groups

▲ **Figure 24.6 Condensed structural formulas and line structures for three cycloalkanes.**

Cycloalkanes

Alkanes that form rings, or cycles, are called **cycloalkanes**. As Figure 24.6 illustrates, cycloalkane structures are sometimes drawn as *line structures*, which are polygons in which each corner represents a CH_2 group. This method of representation is similar to that used for benzene rings. (Section 8.6) (Remember from our discussion of benzene that each vertex in aromatic structures represents a CH group, not a CH_2 group.)

Carbon rings containing fewer than five carbon atoms are strained because the C—C—C bond angles must be less than the 109.5° tetrahedral angle. The amount of strain increases as the rings get smaller. In cyclopropane, which has the shape of an equilateral triangle, the angle is only 60°; this molecule is therefore much more reactive than propane, its straight-chain analog.

Reactions of Alkanes

Because they contain only C—C and C—H bonds, most alkanes are relatively unreactive. At room temperature, for example, they do not react with acids, bases, or strong oxidizing agents. Their low chemical reactivity, as noted in Section 24.1, is due primarily to the strength and lack of polarity of their C—C and C—H bonds.

Alkanes are not completely inert, however. One of their most commercially important reactions is *combustion* in the presence of oxygen leading to the formation of carbon dioxide and water, which is the basis of their use as fuels. (Section 3.2) For example, the complete combustion of ethane proceeds according to the following highly exothermic reaction:

$$2\,C_2H_6(g) + 7\,O_2(g) \longrightarrow 4\,CO_2(g) + 6\,H_2O(l) \quad \Delta H^\circ = -2855\text{ kJ}$$

Self-Assessment Exercises

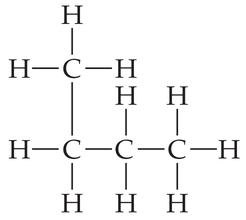
(**ii**) 4-methylhexane
(**iii**) 2,3,4-trimethylpentane

(**a**) i and ii (**b**) i and iii (**c**) ii and iii (**d**) i, ii and iii (**e**) All of these compounds have different molecular formulas, so no two are structural isomers of one another.

SAE 24.7 How would you classify a compound that has the molecular formula C_6H_{12} and contains only C—C and C—H single bonds? (**a**) straight-chain alkane (**b**) branched-chain alkane (**c**) cycloalkane (**d**) aromatic hydrocarbon

SAE 24.8 Which type or types of hydrocarbon do not contain π bonds? (**a**) alkanes (**b**) alkenes (**c**) alkynes (**d**) aromatic hydrocarbons (**e**) alkanes and aromatic hydrocarbons

SAE 24.9 The name of the compound with the structural formula shown here is ______. This compound has ______ structural isomers.



(a) 1-methylpropane, 1 **(b)** 1-methylpropane, 2 **(c)** *n*-butane, 0 **(d)** *n*-butane, 1 **(e)** *n*-butane, 2

SAE 24.10 Which reaction describes the combustion of *n*-pentane?

(a) $C_5H_{10}(l) \longrightarrow 5\,C(s) + 5\,H_2(g)$
(b) $2\,C_5H_{10}(l) + 15\,O_2(g) \longrightarrow 10\,CO_2(g) + 10\,H_2O(g)$
(c) $C_5H_{12}(l) + 8\,O_2(g) \longrightarrow 5\,CO_2(g) + 6\,H_2O(g)$
(d) $C_5H_{12}(l) + 5\,O_2(g) \longrightarrow 5\,CO_2(g) + 6\,H_2(g)$

24.3 Alkenes, Alkynes, and Aromatic Hydrocarbons

Because alkanes have only single bonds, they contain the largest possible number of hydrogen atoms per carbon atom. As a result, they are called *saturated hydrocarbons*. Alkenes, alkynes, and aromatic hydrocarbons contain multiple carbon–carbon bonds (double bonds, triple bonds, or delocalized π bonds). As a result, they contain fewer hydrogen atoms than an alkane with the same number of carbon atoms. Collectively, they are called *unsaturated hydrocarbons*. On the whole, unsaturated molecules are more reactive than saturated ones.

Learning Objectives

When you finish Section 24.3, you should be able to:

- Interconvert between the structural formula and the name of an alkene or an alkyne.
- Identify structural isomers of alkenes and alkynes.
- Identify and name geometric isomers of alkenes and explain why such isomers are not usually encountered in alkanes or alkynes.
- Predict the products of addition reactions involving alkenes and alkynes.
- Describe the differences in the reactivities of alkenes and aromatic hydrocarbons.

Alkenes

Alkenes are unsaturated hydrocarbons that contain at least one C═C bond. The simplest alkene is $CH_2{=}CH_2$, called ethene (IUPAC) or ethylene (common name), which plays important roles as a plant hormone in seed germination and fruit ripening. The next member of the series is $CH_3{-}CH{=}CH_2$, called propene or propylene. Alkenes with four or more carbon atoms have several isomers. For example, the alkene C_4H_8 has the four structural isomers shown in **Figure 24.7**. Notice both their structures and their names.

The names of alkenes are based on the longest continuous chain of carbon atoms that contains the double bond. The chain is named by changing the ending of the name of the corresponding alkane from *-ane* to *-ene*. The compound on the left in Figure 24.7, for example, has a double bond as part of a three-carbon chain; thus, the parent alkene is propene.

Go Figure How many isomers are there for propene, C_3H_6?

trans isomer

▲ **Figure 24.8** **Cis and trans isomers of alkenes.** Geometric isomers of alkenes exist because rotation about a carbon–carbon double bond requires too much energy to occur at ordinary temperatures.

The location of the double bond along an alkene chain is indicated by a prefix number that designates the double-bond carbon atom that is nearest an end of the chain. The chain is always numbered from the end that brings us to the double bond sooner and hence gives the smallest-numbered prefix. In propene, the only possible location for the double bond is between the first and second carbons; thus, a prefix indicating its location is unnecessary. For butene (Figure 24.7), there are two possible positions for the double bond, either after the first carbon (1-butene) or after the second carbon (2-butene).

If a substance contains two or more double bonds, the location of each is indicated by a numerical prefix, and the ending of the name is altered to identify the number of double bonds: diene (two), triene (three), and so forth. For example, $CH_2{=}CH{-}CH_2{-}CH{=}CH_2$ is 1,4-pentadiene.

The two isomers on the right in Figure 24.7 differ in the relative locations of their methyl groups. These two compounds are geometric isomers, compounds that have the same molecular formula and the same groups bonded to one another but differ in the spatial arrangement of these groups. (Section 23.4) In the cis isomer, the two methyl groups are on the same side of the double bond, whereas in the trans isomer they are on opposite sides. Geometric isomers possess distinct physical properties and can differ significantly from each other in their chemical behavior.

Geometric isomerism in alkenes arises because, unlike the $C{-}C$ bond, the $C{=}C$ bond resists twisting. Recall from Section 9.6 that the double bond between two carbon atoms consists of a σ and a π bond. **Figure 24.8** shows a cis alkene. The carbon–carbon bond axis and the bonds to the hydrogen atoms and to the alkyl groups (designated R) are all in a plane, and the p orbitals that form the π bond are perpendicular to that plane. As Figure 24.8 shows, rotation around the carbon–carbon double bond requires the π bond to be broken, a process that requires considerable energy (about 250 kJ/mol). Because rotation does not occur easily around the carbon–carbon bond, the cis and trans isomers of an alkene cannot readily interconvert; therefore, they are considered distinct compounds.

Sample Exercise 24.1

Drawing Isomers

Draw all the structural and geometric isomers of pentene, C_5H_{10}, that have an unbranched hydrocarbon chain.

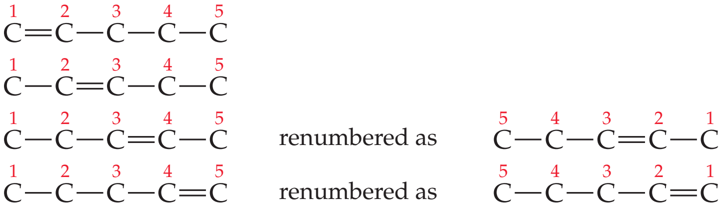
SOLUTION

Analyze We are asked to draw all the isomers (both structural and geometric) for an alkene with a five-carbon chain.

Plan Because the compound is named pentene and not pentadiene or pentatriene, we know that the five-carbon chain contains only one carbon–carbon double bond. Thus, we begin by placing the double bond in various locations along the chain, remembering that the chain can be numbered from either end. After finding the different unique locations for the double bond, we consider whether the molecule can have cis and trans isomers.

Solve

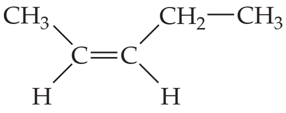
There can be a double bond after either the first carbon (1-pentene) or second carbon (2-pentene). These are the only two possibilities because the chain can be numbered from either end. Thus, what we might erroneously call 3-pentene is actually 2-pentene, as seen by numbering the carbon chain from the other end:



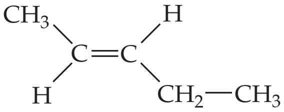
Because the first C atom in 1-pentene is bonded to two H atoms, there are no cis–trans isomers. There are cis and trans isomers for 2-pentene, however. Thus, the three isomers for pentene are:

$CH_2{=}CH{-}CH_2{-}CH_2{-}CH_3$

1-Pentene



cis-2-Pentene



trans-2-Pentene

Comment Convince yourself that *cis*-3-pentene is identical to *cis*-2-pentene and that *trans*-3-pentene is identical to *trans*-2-pentene. The correct names, however, are *cis*-2-pentene and *trans*-2-pentene because they have smaller numbered prefixes.

▶ Practice Exercise

How many straight-chain isomers are there of hexene, C_6H_{12}?

Alkynes

Alkynes are unsaturated hydrocarbons containing one or more $C{\equiv}C$ bonds. The simplest alkyne is acetylene (C_2H_2, systematic name ethyne), a highly reactive molecule. When acetylene is burned in a stream of oxygen in an oxyacetylene torch, the flame reaches about 3200 K. Because alkynes in general are highly reactive, they are not as widely distributed in nature as alkenes. They are, however, important intermediates in many industrial processes.

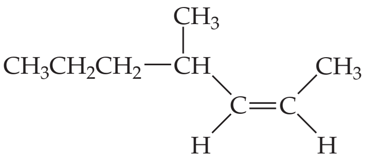
Alkynes are named by identifying the longest continuous chain containing the triple bond and modifying the ending of the name of the corresponding alkane from *-ane* to *-yne*, as shown in Sample Exercise 24.2.

Sample Exercise 24.2

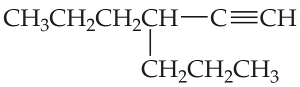
Naming Unsaturated Hydrocarbons

Name the following compounds:

(a)



(b)



$$CH_3CH_2CH_2\underset{\displaystyle CH_2CH_2CH_3}{\underset{|}{C}H}{-}C{\equiv}CH$$

SOLUTION

Analyze We are given the condensed structural formulas for an alkene and an alkyne and asked to name the compounds.

Plan In each case, the name is based on the number of carbon atoms in the longest continuous carbon chain that contains the multiple bond. In the alkene, care must be taken to indicate whether cis–trans isomerism is possible and, if so, which isomer is given.

Solve

(a) The longest continuous chain of carbons that contains the double bond is seven carbons long, so the parent hydrocarbon is heptene. Because the double bond begins at carbon 2 (numbering from the end closer to the double bond), we have 2-heptene. With a methyl group at carbon atom 4, we have 4-methyl-2-heptene. The geometrical configuration at the double bond is cis (that is, the alkyl groups are bonded to the double bond on the same side). Thus, the full name is 4-methyl-*cis*-2-heptene.

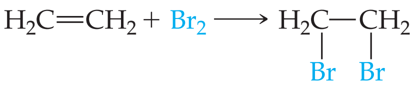
(b) The longest continuous chain containing the triple bond has six carbons, so this compound is a derivative of hexyne. The triple bond comes after the first carbon (numbering from the right), making it 1-hexyne. The branch from the hexyne chain contains three carbon atoms, making it a propyl group. Because this substituent is located on C3 of the hexyne chain, the molecule is 3-propyl-1-hexyne.

▶ Practice Exercise

Draw the condensed structural formula for 4-methyl-2-pentyne.

Addition Reactions of Alkenes and Alkynes

The presence of carbon–carbon double or triple bonds in hydrocarbons markedly increases their chemical reactivity. The most characteristic reactions of alkenes and alkynes are **addition reactions**, in which a reactant is added to the two atoms that form the multiple bond. A simple example is the addition of elemental bromine to ethylene to produce 1,2-dibromoethane:



$$H_2C{=}CH_2 + Br_2 \longrightarrow \underset{Br}{\underset{|}{H_2C}}{-}\underset{Br}{\underset{|}{CH_2}} \qquad [24.1]$$

The π bond in ethylene is broken, and the electrons that formed the bond are used to form two σ bonds to the two bromine atoms. The σ bond between the carbon atoms is retained.

Addition of H_2 to an alkene converts it to an alkane:

$$CH_3CH{=}CHCH_3 + H_2 \xrightarrow{\text{Ni, 500 °C}} CH_3CH_2CH_2CH_3 \qquad [24.2]$$

The reaction between an alkene and H_2, referred to as *hydrogenation*, does not occur readily at ordinary temperatures and pressures. One reason for the lack of reactivity of H_2 toward alkenes is the stability of the H_2 bond. To promote the reaction, the reaction temperature must be raised (500 °C), and a catalyst (such as Ni) is used to assist in rupturing the H—H bond. We write such conditions over the reaction arrow to indicate they must be present in order for the reaction to occur. The most widely used catalysts are finely divided metals on which H_2 is adsorbed. (Section 14.6)

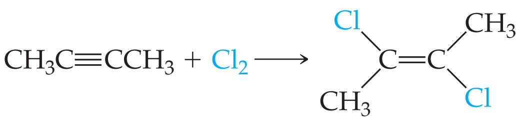
Hydrogen halides and water can also add to the double bond of alkenes, as in the following reactions of ethylene:

$$CH_2{=}CH_2 + HBr \longrightarrow CH_3CH_2Br \qquad [24.3]$$

$$CH_2{=}CH_2 + H_2 \xrightarrow{H_2SO_4} CH_3CH_2OH \qquad [24.4]$$

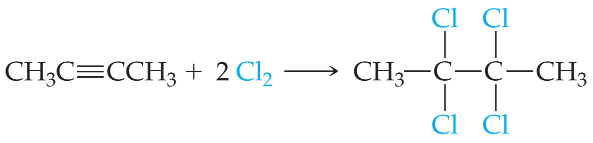
The addition of water is catalyzed by a strong acid, such as H_2SO_4.

The addition reactions of alkynes resemble those of alkenes, as shown in the following examples:



[24.5]

2-Butyne *trans*-2,3-Dichloro-2-butene



$$CH_3C{\equiv}CCH_3 + 2\,Cl_2 \longrightarrow CH_3{-}\overset{Cl}{\overset{|}{\underset{Cl}{\underset{|}{C}}}}{-}\overset{Cl}{\overset{|}{\underset{Cl}{\underset{|}{C}}}}{-}CH_3 \qquad [24.6]$$

2-Butyne 2,2,3,3-Tetrachlorobutane

Sample Exercise 24.3

Predicting the Product of an Addition Reaction

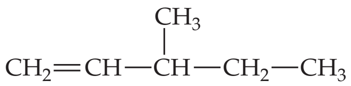
Write the condensed structural formula for the product of the hydrogenation of 3-methyl-1-pentene.

SOLUTION

Analyze We are asked to predict the compound formed when a particular alkene undergoes hydrogenation (reaction with H_2) and to write the condensed structural formula of the product.

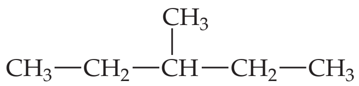
Plan To determine the condensed structural formula of the product, we must first write the condensed structural formula or Lewis structure of the reactant. In the hydrogenation of the alkene, H_2 adds to the double bond, producing an alkane.

Solve The name of the starting compound tells us that we have a chain of five C atoms with a double bond at one end (position 1) and a methyl group on C3:



$$CH_2{=}CH{-}\overset{CH_3}{\overset{|}{CH}}{-}CH_2{-}CH_3$$

Hydrogenation—the addition of two H atoms to the carbons of the double bond—leads to the following alkane:



$$CH_3{-}CH_2{-}\underset{}{\overset{\displaystyle CH_3}{\overset{|}{C}H}}{-}CH_2{-}CH_3$$

Comment The longest chain in this alkane has five carbon atoms; the product is therefore 3-methylpentane.

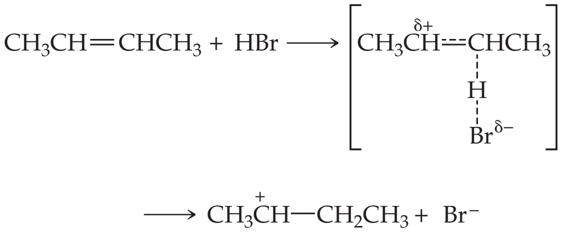
▶ Practice Exercise

Addition of HCl to an alkene forms 2-chloropropane. What is the alkene?

A CLOSER LOOK Mechanism of Addition Reactions

As the understanding of chemistry has grown, chemists have advanced from simply cataloging reactions that occur to explaining *how* they occur, by drawing the individual steps of a reaction based upon experimental and theoretical evidence. The sum of these steps is called a *reaction mechanism*. (Section 14.5)

The addition reaction between HBr and an alkene, for instance, is thought to proceed in two steps. In the first step, which is rate determining (Section 14.6), HBr attacks the electron-rich double bond, transferring a proton to one of the double-bond carbons. In the reaction of 2-butene with HBr, for example, the first step is

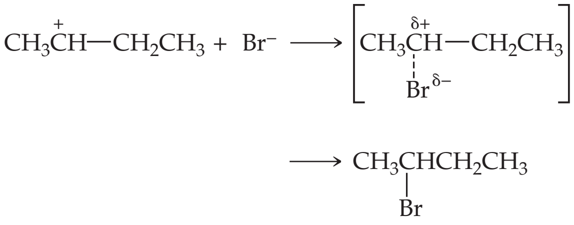


$$CH_3CH{=}CHCH_3 + HBr \longrightarrow \left[\begin{array}{l} CH_3\overset{\delta+}{C}H{\cdots}CHCH_3 \\ \qquad\quad \vdots \\ \qquad\quad H \\ \qquad\quad \vdots \\ \qquad\quad Br^{\delta-} \end{array}\right] \longrightarrow CH_3\overset{+}{C}H{-}CH_2CH_3 + Br^-$$

[24.7]

The electron pair that formed the π bond is used to form the new C—H bond.

The second, faster step is addition of Br^- to the positively charged carbon. The bromide ion donates a pair of electrons to the carbon, forming the C—Br bond:



$$CH_3\overset{+}{C}H{-}CH_2CH_3 + Br^- \longrightarrow \left[\begin{array}{l} CH_3\overset{\delta+}{C}H{-}CH_2CH_3 \\ \qquad\;\; \vdots \\ \qquad\;\; Br^{\delta-} \end{array}\right] \longrightarrow CH_3\underset{\displaystyle Br}{\underset{|}{C}}HCH_2CH_3$$

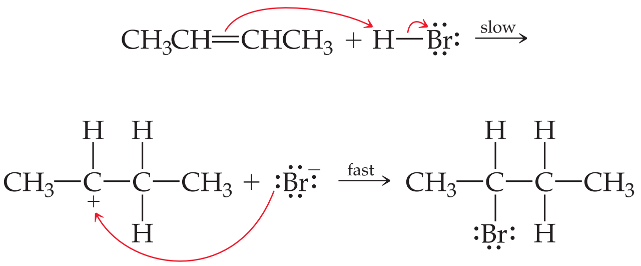
[24.8]

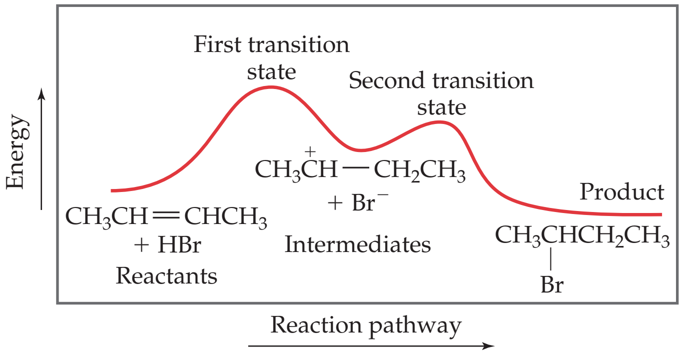
Because the rate-determining step involves both the alkene and the acid, the rate law for the reaction is second order, first order in the alkene and first order in HBr:

$$\text{Rate} = -\frac{\Delta[CH_3CH{=}CHCH_3]}{\Delta t} = k[CH_3CH{=}CHCH_3][HBr] \qquad [24.9]$$

The energy profile for the reaction is shown in **Figure 24.9**. The first energy maximum represents the transition state in the first step, and the second maximum represents the transition state in the second step. The energy minimum represents the energies of the intermediate species, $CH_3\overset{+}{C}H{-}CH_2CH_3$ and Br^-.

To show electron movement in reactions like these, chemists often use curved arrows pointing in the direction of electron flow. For the addition of HBr to 2-butene, for example, the shifts in electron positions are shown as

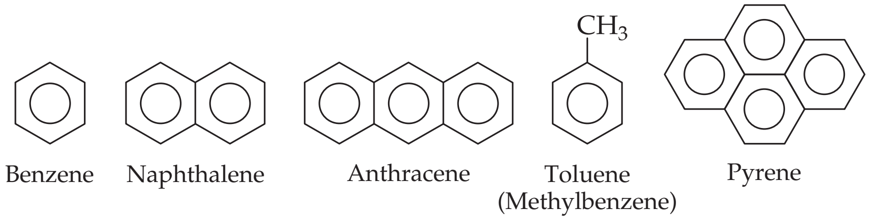




▲ **Figure 24.9 Energy profile for addition of HBr to 2-butene.** The two maxima tell you that this is a two-step mechanism.

Aromatic Hydrocarbons

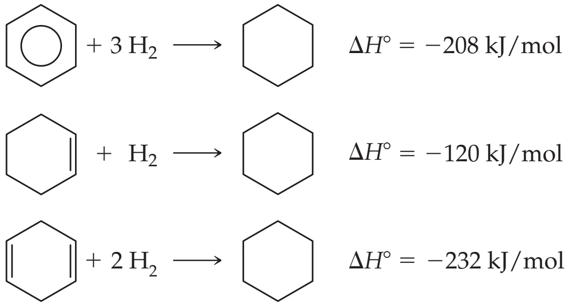
The simplest aromatic hydrocarbon, benzene (C_6H_6), is shown in **Figure 24.10** along with some other aromatic hydrocarbons. Benzene is the most important aromatic hydrocarbon, and most of our discussion focuses on it. When the C_6H_5-group is a substituent in a compound, it is known (somewhat confusingly) as the **phenyl** group.



▲ **Figure 24.10 Line formulas and common names of several aromatic compounds.** The aromatic rings are represented by hexagons with a circle inscribed inside to denote delocalized π bonds. Each vertex represents a carbon atom. Each carbon is bound to three other atoms—either three carbons, or two carbons and a hydrogen—so that each carbon has the requisite four bonds.

If you draw one Lewis structure for benzene, you draw a ring that contains three $C{=}C$ double bonds and three single $C{-}C$ bonds. (Section 8.6) You might therefore expect benzene to resemble the alkenes and to be highly reactive. Benzene and the other aromatic hydrocarbons, however, are much more stable than alkenes because the π electrons are delocalized in the π orbitals. (Section 9.6)

We can estimate the stabilization of the π electrons in benzene by comparing the energy released upon forming cyclohexane by adding hydrogen to benzene, to cyclohexene (one double bond), and to 1,4-cyclohexadiene (two double bonds):

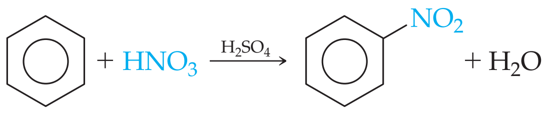


$+ 3\,H_2 \longrightarrow$
$\Delta H^\circ = -208$ kJ/mol
$+ H_2 \longrightarrow$
$\Delta H^\circ = -120$ kJ/mol
$+ 2\,H_2 \longrightarrow$
$\Delta H^\circ = -232$ kJ/mol

Notice that in the second and third reactions, we are hydrogenating one and two $C{=}C$ double bonds, respectively. It therefore appears that the energy released upon hydrogenation of each double bond is roughly 116–120 kJ/mol for each bond. Benzene contains the equivalent of three double bonds. We might expect, therefore, the energy released upon hydrogenation of the three double bonds in benzene to be roughly 348–360 kJ/mol, if benzene behaved as though it were "cyclohexatriene"—that is, if it behaved as though it had three isolated double bonds in a ring. Instead, the energy released is only 208 kJ, indicating that benzene is more stable than would be expected for three double bonds. The difference of 140–152 kJ/mol between the expected heat of hydrogenation and the observed heat of hydrogenation is due to stabilization of the π electrons through delocalization in the π orbitals that extend around the ring. Chemists call this stabilization energy the *resonance energy*.

Substitution Reactions of Aromatic Hydrocarbons

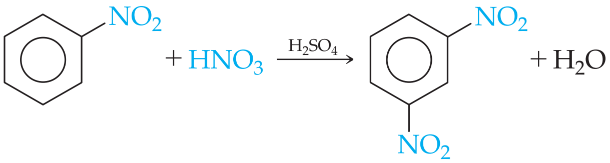
Although aromatic hydrocarbons are unsaturated, *they do not readily undergo addition reactions*. The delocalized π bonding causes aromatic compounds to behave quite differently from alkenes and alkynes. For example, benzene does not add Cl_2 or Br_2 to its double bonds under ordinary conditions. In contrast, aromatic hydrocarbons undergo **substitution reactions** relatively easily. In a substitution reaction, one hydrogen atom of the molecule is removed and replaced (substituted) by another atom or group of atoms. When benzene is warmed in a mixture of nitric and sulfuric acids, for example, one of the benzene hydrogens is replaced by the nitro group, NO_2:



[24.10]

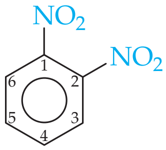
Benzene Nitrobenzene

More vigorous treatment results in substitution of a second nitro group into the molecule:

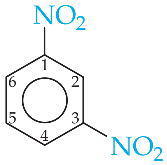


[24.11]

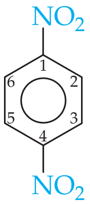
There are three isomers of benzene that contain two nitro groups—the 1,2- or *ortho*-isomer, the 1,3- or *meta*-isomer, and the 1,4- or *para*-isomer of dinitrobenzene:



ortho-Dinitrobenzene
1,2-Dinitrobenzene
mp 118 °C



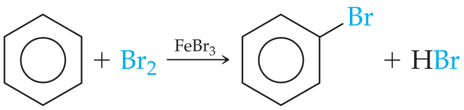
meta-Dinitrobenzene
1,3-Dinitrobenzene
mp 90 °C



para-Dinitrobenzene
1,4-Dinitrobenzene
mp 174 °C

In the reaction of Equation 24.11, the principal product is the *meta* isomer.

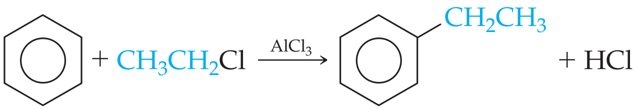
Bromination of benzene, carried out with $FeBr_3$ as a catalyst, is another substitution reaction:



[24.12]

Benzene Bromobenzene

In a similar substitution reaction, called the *Friedel–Crafts reaction*, alkyl groups can be substituted onto an aromatic ring by reacting an alkyl halide with an aromatic compound in the presence of $AlCl_3$ as a catalyst:



[24.13]

Benzene Ethylbenzene

Self-Assessment Exercises

(**i**) 1,3-dibromo-2-butene
(**ii**) 1,1-dibromo-1-butene

(**a**) only i (**b**) only ii (**c**) both i and ii (**d**) Neither compound has geometric isomers.

SAE 24.13 Which of the following statements about addition reactions is *false*? (**a**) Alkenes, alkynes, and aromatic hydrocarbons undergo similar addition reactions. (**b**) Alkenes can undergo addition reactions with elemental halogens. (**c**) The addition of hydrogen to an alkene produces an alkane. (**d**) The addition of water to an alkene produces an alcohol.

SAE 24.14 How many isomers, both structural and geometric, exist for an alkene with the molecular formula C_3H_5Cl? (**a**) two (**b**) three (**c**) four (**d**) more than four (**e**) There are no isomers, only one alkene has this molecular formula.

SAE 24.15 What is the product of the reaction between 3-methyl-2-pentene and elemental bromine? Neglect any possible geometrical isomerism. (**a**) 1,2-dibromo-3-methylpentane (**b**) 2,3-dibromo-3-methylpentane (**c**) 2-bromo-3-methylpentane (**d**) 3-bromo-3-methylpentane (**e**) 3-methyl-pentane

24.4 | Organic Functional Groups

Learning Objectives

When you finish Section 24.4, you should be able to:

- Recognize and name different organic functional groups from inspection of the structural formula of an organic compound.
- Identify the functional group(s) present in an organic compound from the name of the compound.
- Determine the products of simple chemical reactions involving organic compounds.

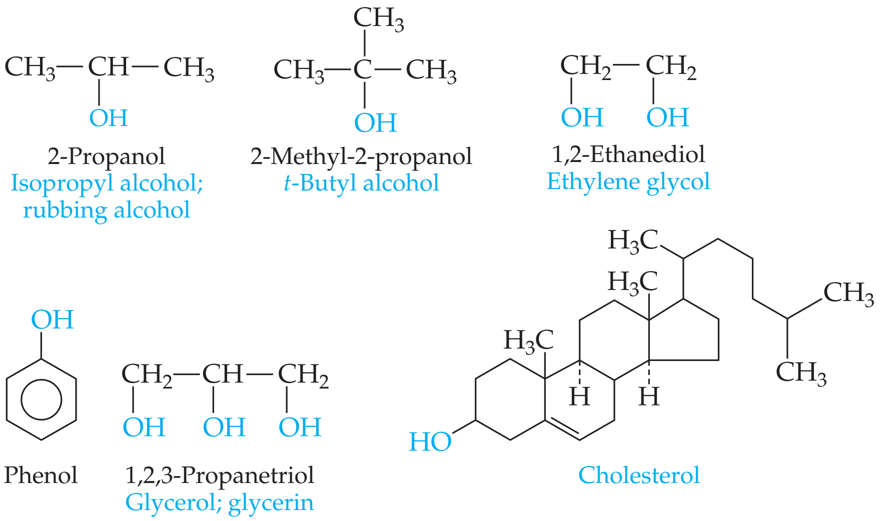
The $C{=}C$ double bonds of alkenes and the $C{\equiv}C$ triple bonds of alkynes are just two of many functional groups in organic molecules. As noted previously, these functional groups each undergo characteristic reactions, and the same is true of all other functional groups. Each kind of functional group often undergoes the same kinds of reactions in every molecule, regardless of the size and complexity of the molecule. Thus, the chemistry of an organic molecule is largely determined by the functional groups it contains. Table 24.2 lists the most common functional groups. Notice that, except for $C{=}C$ and $C{\equiv}C$, they all contain either O, N, or a halogen atom, X.

We can think of organic molecules as being composed of functional groups bonded to one or more alkyl groups. The alkyl groups, which are made of $C{-}C$ and $C{-}H$ single bonds, are the less reactive portions of the molecules. In describing general features of organic compounds, chemists often use the designation R to represent any alkyl group: methyl, ethyl, propyl, and so on. Alkanes, for example, which contain no functional group, are represented as $R{-}H$. Alcohols, which contain the functional group $-OH$, are represented as $R{-}OH$. If two or more different alkyl groups are present in a molecule, we designate them R, R′, R″, and so forth.

Alcohols

Alcohols are compounds in which one or more hydrogens of a parent hydrocarbon have been replaced by the functional group $-OH$, called either the *hydroxyl group* or the *alcohol group*. Note in Figure 24.11 that the name for an alcohol ends in *-ol*. The simple alcohols are named by changing the last letter in the name of the corresponding alkane to *-ol*. For example, ethan*e* becomes ethan*ol*. Where necessary, the location of the OH group is designated by a numeric prefix that indicates the number of the carbon atom bearing the OH group. Figure 24.12 shows several commercial products that consist entirely or in large part of an alcohol.

The $O{-}H$ bond is polar, so alcohols are more soluble in polar solvents than are hydrocarbons. The $-OH$ functional group can also participate in hydrogen bonding. As a result, the boiling points of alcohols are higher than those of their parent alkanes.



2-Propanol
Isopropyl alcohol; rubbing alcohol

2-Methyl-2-propanol
t-Butyl alcohol

1,2-Ethanediol
Ethylene glycol

Phenol

Nite Time
Isopropyl Alcohol

▲ **Figure 24.12 Everyday alcohols.** Many of the products we use every day—from rubbing alcohol to hair spray and antifreeze—are composed either entirely or mainly of alcohols.

TABLE 24.2 Common Functional Groups

			Example		
Functional Group	**Compound Type**	**Suffix**	**Structural Formula**	**Ball-and-stick Model**	**Systematic Name** (Common Name)
	Alkene	*-ene*			Ethene (Ethylene)
—C≡C—	Alkyne	*-yne*	H—C≡C—H		Ethyne (Acetylene)
	Alcohol	*-ol*			Methanol (Methyl alcohol)
	Ether	*ether*			Methoxymethane (Dimethyl ether)
 (X = halogen)	Alkyl halide or haloalkane	*-ide*			Chloromethane (Methyl chloride)
	Amine	*-amine*			Ethylamine
	Aldehyde	*-al*			Ethanal (Acetaldehyde)
	Ketone	*-one*			Propanone (Acetone)
	Carboxylic acid	*-oic acid*			Ethanoic acid (Acetic acid)
	Ester	*-oate*			Methyl ethanoate (Methyl acetate)
	Amide	*-amide*			Ethanamide (Acetamide)

The simplest alcohol, methanol (methyl alcohol), has many industrial uses and is produced on a large scale by heating carbon monoxide and hydrogen under pressure in the presence of a metal oxide catalyst:

$$CO(g) + 2\,H_2(g) \xrightarrow[400\,^\circ C]{200-300\,\text{atm}} CH_3OH(g) \qquad [24.14]$$

Because methanol has a very high octane rating as an automobile fuel, it is used as a gasoline additive and as a fuel in its own right.

Ethanol (ethyl alcohol, C_2H_5OH) is a product of the fermentation of carbohydrates such as sugars and starches. In the absence of air, yeast cells convert these carbohydrates into ethanol and CO_2:

$$C_6H_{12}O_6(aq) \xrightarrow{\text{yeast}} 2\,C_2H_5OH(aq) + 2\,CO_2(g) \qquad [24.15]$$

In the process, the yeast cells derive energy necessary for growth. This reaction is carried out under carefully controlled conditions to produce beer, wine, and other beverages in which ethanol (called just "alcohol" in everyday language) is the active ingredient.

The simplest polyhydroxyl alcohol (an alcohol containing more than one OH group) is 1,2-ethanediol (ethylene glycol, $HOCH_2CH_2OH$), the major ingredient in automobile antifreeze. Another common polyhydroxyl alcohol is 1,2,3-propanetriol (glycerol, $HOCH_2CH(OH)CH_2OH$), a viscous liquid that dissolves readily in water and is used in cosmetics as a skin softener and in foods and candies to keep them moist.

Phenol is the simplest compound with an OH group attached to an aromatic ring. One of the most striking effects of the aromatic group is the greatly increased acidity of the OH group. Phenol is about 1 million times more acidic in water than a nonaromatic alcohol. Even so, it is not a very strong acid ($K_a = 1.3 \times 10^{-10}$). Phenol is used industrially to make plastics and dyes, and as a topical anesthetic in throat sprays.

Cholesterol, shown in Figure 24.11, is a biochemically important alcohol. The OH group forms only a small component of this molecule, so cholesterol is only slightly soluble in water (2.6 g/L of H_2O). Cholesterol is a normal and essential component of our bodies; when present in excessive amounts, however, it may precipitate from solution. It precipitates in the gallbladder to form crystalline lumps called *gallstones*. It may also precipitate against the walls of veins and arteries and thus contribute to high blood pressure and other cardiovascular problems.

Ethers

Compounds in which two hydrocarbon groups are bonded to one oxygen are called **ethers**. Ethers can be formed from two molecules of alcohol by eliminating a molecule of water. The reaction is catalyzed by sulfuric acid, which takes up water to remove it from the system:

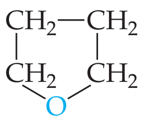
$$CH_3CH_2{-}OH + H{-}OCH_2CH_3 \xrightarrow{H_2SO_4} CH_3CH_2{-}O{-}CH_2CH_3 + H_2O \qquad [24.16]$$

A reaction in which water is eliminated from two substances is called a *condensation reaction*. (Sections 12.6 and 22.8)

Both diethyl ether and the cyclic ether tetrahydrofuran are common solvents for organic reactions:

$$CH_3CH_2{-}O{-}CH_2CH_3$$

Diethyl ether



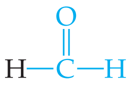
Tetrahydrofuran (THF)

Diethyl ether was formerly used as an anesthetic (known simply as "ether" in that context), but its use was discontinued because it had significant side effects.

Aldehydes and Ketones

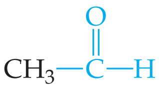
Several of the functional groups listed in Table 24.2 contain the **carbonyl group**, C=O. This group, together with the atoms attached to its carbon, defines several important functional groups that we consider in this section.

In **aldehydes**, the carbonyl group has at least one hydrogen atom attached:



$$H-\overset{O}{\overset{\|}{C}}-H$$

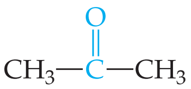
Methanal
Formaldehyde



$$CH_3-\overset{O}{\overset{\|}{C}}-H$$

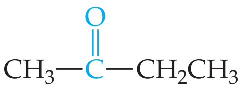
Ethanal
Acetaldehyde

In **ketones**, the carbonyl group occurs at the interior of a carbon chain and is therefore flanked by carbon atoms:



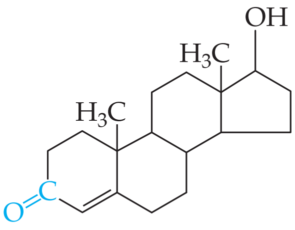
$$CH_3-\overset{O}{\overset{\|}{C}}-CH_3$$

Propanone
Acetone



$$CH_3-\overset{O}{\overset{\|}{C}}-CH_2CH_3$$

2-Butanone
Methyl ethyl ketone



Testosterone

The systematic names of aldehydes contain -*al* and ketone names contain -*one*. Notice that testosterone has both alcohol and ketone groups; the ketone functional group dominates the molecular properties. Therefore, testosterone is considered a ketone first and an alcohol second, and its name reflects its ketone properties.

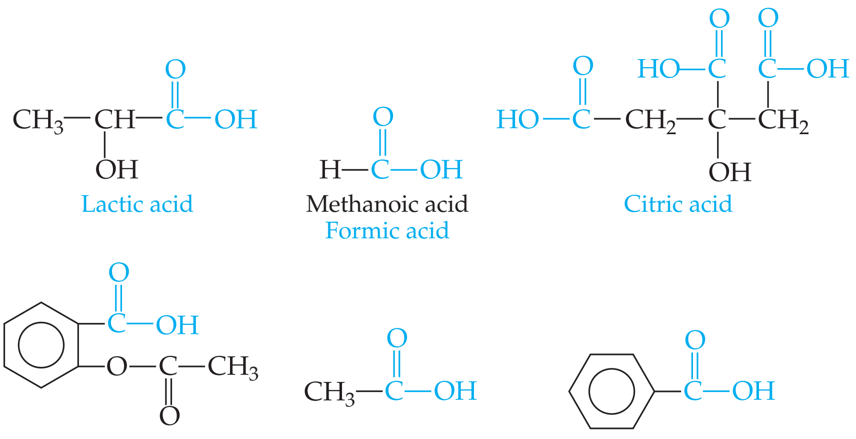
Many compounds found in nature contain an aldehyde or ketone functional group. Vanilla and cinnamon flavorings are naturally occurring aldehydes. Two isomers of the ketone carvone impart the characteristic flavors of spearmint leaves and caraway seeds.

Ketones are less reactive than aldehydes and are used extensively as solvents. Acetone (propanone), the most widely used ketone, is completely miscible with water, yet it dissolves a wide range of organic substances.

Carboxylic Acids and Esters

Carboxylic acids contain the *carboxyl* functional group, often written COOH. (Section 16.10) These weak acids are widely distributed in nature and are common in many fruits. They are also important in the manufacture of polymers used to make fibers, films, and paints. **Figure 24.13** shows the formulas of several carboxylic acids.

Go Figure Which of these substances have both a carboxylic acid functional group and an alcohol functional group?



Lactic acid

Methanoic acid
Formic acid

Citric acid

Acetylsalicylic acid
Aspirin

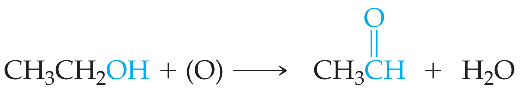
Ethanoic acid
Acetic acid

Phenyl methanoic acid
Benzoic acid

▲ **Figure 24.13** **Structural formulas of common carboxylic acids.** The common names for these acids are given in blue type.

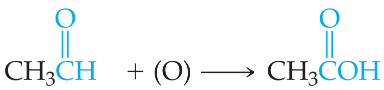
The common names of many carboxylic acids are based on their historical origins. Formic acid, for example, was first prepared by extraction from ants; its name is derived from the Latin word for “ant,” *formica*.

Carboxylic acids can be produced by oxidation of alcohols. Under appropriate conditions, the aldehyde may be isolated as the first product of oxidation, as in the sequence



$$CH_3CH_2OH + (O) \longrightarrow CH_3\overset{\overset{O}{\|}}{C}H + H_2O \qquad [24.17]$$

Ethanol Acetaldehyde

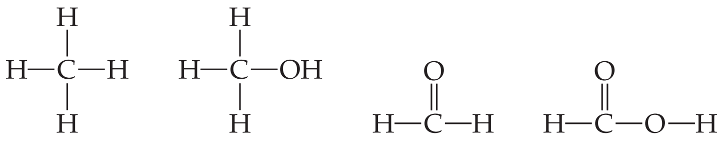


$$CH_3\overset{\overset{O}{\|}}{C}H + (O) \longrightarrow CH_3\overset{\overset{O}{\|}}{C}OH \qquad [24.18]$$

Acetaldehyde Acetic acid

where (O) represents any oxidant that can provide oxygen atoms. The air oxidation of ethanol to acetic acid is responsible for causing wines to turn sour, producing vinegar.

The oxidation processes in organic compounds are related to those oxidation reactions we studied in Chapter 20. Instead of counting electrons, the number of C—O bonds is usually considered to show the extent of oxidation of similar compounds. For example, methane can be oxidized to methanol; further oxidation leads to formaldehyde (methanal) and then formic acid (methanoic acid):



Methane Methanol Formaldehyde Formic acid

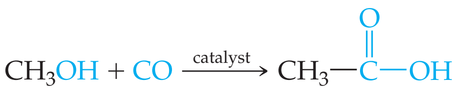
From methane to formic acid, the number of C—O bonds increases from 0 to 3 (double bonds are counted as two). If you were to calculate the oxidation state of carbon in these compounds, it would range from -4 in methane (if H’s are counted as $+1$) to $+2$ in formic acid, which is consistent with carbon being oxidized. The ultimate oxidation product of any organic compound, then, is CO_2, which is indeed the product of combustion reactions of carbon-containing compounds (CO_2 has 4 C—O bonds, and C has the oxidation state $+4$).

Aldehydes and ketones can be prepared by controlled oxidation of alcohols. Complete oxidation results in formation of CO_2 and H_2O, as in the burning of methanol:

$$2\,CH_3OH(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 4\,H_2O(g)$$

Controlled partial oxidation to form other organic substances, such as aldehydes and ketones, is carried out by using various oxidizing agents, such as air, hydrogen peroxide (H_2O_2), ozone (O_3), and potassium dichromate ($K_2Cr_2O_7$).

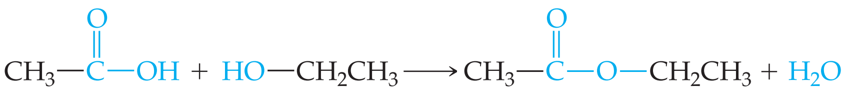
Acetic acid can also be produced by the reaction of methanol with carbon monoxide in the presence of a rhodium catalyst:



$$CH_3OH + CO \xrightarrow{\text{catalyst}} CH_3{-}\overset{\overset{O}{\|}}{C}{-}OH \qquad [24.19]$$

This reaction is not an oxidation; it involves, in effect, the insertion of a carbon monoxide molecule between the CH_3 and OH groups. A reaction of this kind is called *carbonylation*.

Carboxylic acids can undergo condensation reactions with alcohols to form esters:

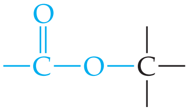


$$CH_3{-}\overset{\overset{O}{\|}}{C}{-}OH + HO{-}CH_2CH_3 \longrightarrow CH_3{-}\overset{\overset{O}{\|}}{C}{-}O{-}CH_2CH_3 + H_2O$$

Acetic acid Ethanol Ethyl acetate

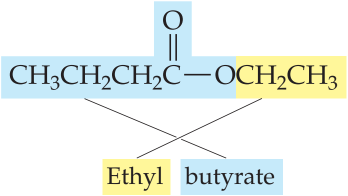
[24.20]

Esters are compounds in which the H atom of a carboxylic acid is replaced by a carbon-containing group:



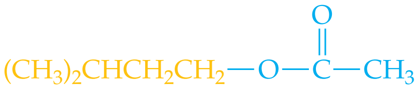
$$-\overset{\overset{\displaystyle O}{\|}}{C}-O-\overset{|}{\underset{|}{C}}-$$

The name of any ester consists of the name of the group contributed by the alcohol followed by the name of the group contributed by the carboxylic acid, with the *-ic* replaced by *-ate*. For example, the ester formed from ethyl alcohol, CH_3CH_2OH, and butyric acid, $CH_3CH_2CH_2COOH$, is



$$CH_3CH_2CH_2\overset{\overset{\displaystyle O}{\|}}{C}-OCH_2CH_3$$

Notice that the chemical formula generally has the group originating from the acid written first, which is opposite of the way the ester is named. Another example is isoamyl acetate, the ester formed from acetic acid and isoamyl alcohol. Isoamyl acetate smells like bananas or pears.

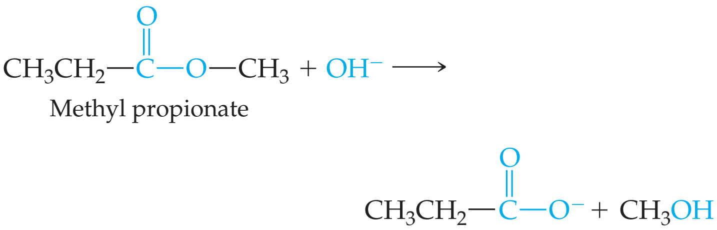


$$(CH_3)_2CHCH_2CH_2-O-\overset{\overset{\displaystyle O}{\|}}{C}-CH_3$$

Isoamyl Acetate

Many esters such as isoamyl acetate have pleasant odors and are largely responsible for the pleasing aromas of many fruits.

An ester treated with an acid or a base in aqueous solution is *hydrolyzed*; that is, the molecule is split into an alcohol and a carboxylic acid or its anion:



$$CH_3CH_2-\overset{\overset{\displaystyle O}{\|}}{C}-O-CH_3 + OH^- \longrightarrow CH_3CH_2-\overset{\overset{\displaystyle O}{\|}}{C}-O^- + CH_3OH \quad [24.21]$$

Methyl propionate

Propionate Methanol [24.21]

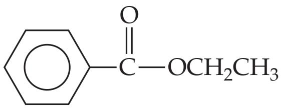
The **hydrolysis** of an ester in the presence of a base is called **saponification**, a term that comes from the Latin word for soap, *sapon*. Naturally occurring esters include fats and oils, and in making soap an animal fat or a vegetable oil is boiled with a strong base. The resultant soap consists of a mixture of salts of long-chain carboxylic acids (called fatty acids), which form during the saponification reaction.

Sample Exercise 24.4

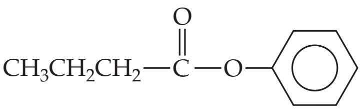
Naming Esters and Predicting Hydrolysis Products

In a basic aqueous solution, esters react with hydroxide ion to form the salt of the carboxylic acid and the alcohol from which the ester is constituted. Name each of the following esters, and indicate the products of their reaction with aqueous base.

(a)



(b)



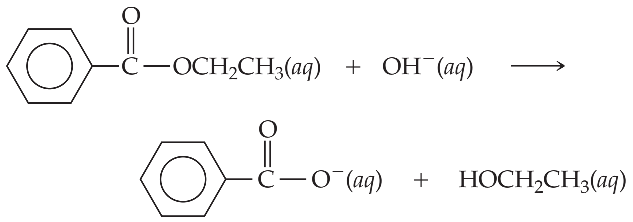
SOLUTION

Analyze We are given two esters and asked to name them and to predict the products formed when they undergo hydrolysis (split into an alcohol and carboxylate ion) in basic solution.

Plan Esters are formed by the condensation reaction between an alcohol and a carboxylic acid. To name an ester, we must analyze its structure and determine the identities of the alcohol and acid from which it is formed. We can identify the alcohol by adding an OH to the alkyl group attached to the O atom of the carboxyl (COO) group. We can identify the acid by adding an H to the O atom of the carboxyl group. We have learned that the first part of an ester name indicates the alcohol portion and the second indicates the acid portion. The name conforms to how the ester undergoes hydrolysis in base, reacting with base to form an alcohol and a carboxylate anion.

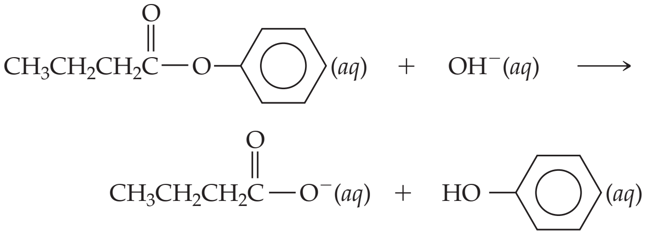
Solve

(**a**) This ester is derived from ethanol (CH_3CH_2OH) and benzoic acid (C_6H_5COOH). Its name is therefore ethyl benzoate. The net ionic equation for reaction of ethyl benzoate with hydroxide ion is



The products are benzoate ion and ethanol.

(**b**) This ester is derived from phenol (C_6H_5) and butanoic acid (commonly called butyric acid) ($CH_3CH_2CH_2COOH$). The residue from the phenol is called the phenyl group. The ester is therefore named phenyl butyrate or phenyl butanoate. The net ionic equation for the reaction of phenyl butyrate with hydroxide ion is



The products are butyrate ion and phenol.

▶ Practice Exercise

Write the condensed structural formula for the ester formed from propyl alcohol and propionic acid.

Amines and Amides

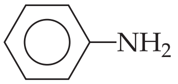
Amines are compounds in which one or more of the hydrogens of ammonia (NH_3) are replaced by an alkyl group:

$CH_3CH_2NH_2$

Ethylamine

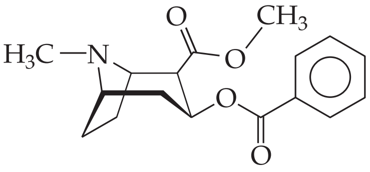
$(CH_3)_3N$

Trimethylamine

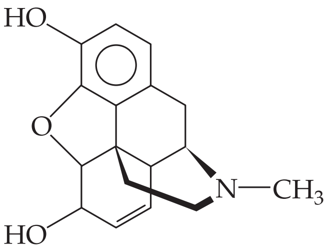


Phenylamine
Aniline

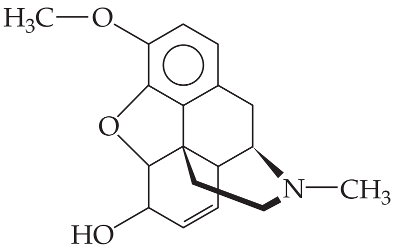
Amines are the most common organic bases. (Section 16.7) As we saw in the “Chemistry and Life” box on “Amines and Amine Hydrochlorides” in Section 16.8, many pharmaceutically active compounds are complex amines:



Cocaine

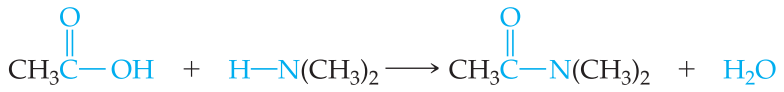


Morphine



Codeine

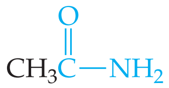
An amine with at least one H bonded to N can undergo a condensation reaction with a carboxylic acid to form an **amide**, which contains the carbonyl group ($C{=}O$) attached to N (Table 24.2):



$$CH_3\overset{O}{\overset{\|}{C}}-OH + H-N(CH_3)_2 \longrightarrow CH_3\overset{O}{\overset{\|}{C}}-N(CH_3)_2 + H_2O$$

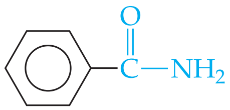
[24.22]

We may consider the amide functional group to be derived from a carboxylic acid with an NRR′, NH_2, or NHR′ group replacing the OH of the acid, as in the following examples:

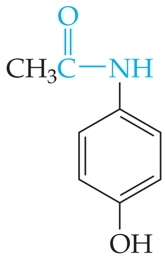


$$CH_3\overset{O}{\overset{\|}{C}}-NH_2$$

Ethanamide
Acetamide

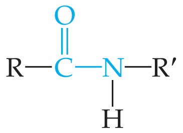


Phenylmethanamide
Benzamide



N-(4-hydroxyphenyl)ethanamide
Acetaminophen

The amide linkage



$$R-\overset{O}{\overset{\|}{C}}-\underset{H}{\underset{|}{N}}-R'$$

where R and R′ are organic groups, is the key functional group in proteins, as discussed in Section 24.7.

Self-Assessment Exercises

SAE 24.16 Consider the reaction $ROH + R'OH \longrightarrow ROR' + H_2O$, where R and R′ are generic alkyl groups. This is an example of ______ reaction and the product is ______. (**a**) a condensation, an ester (**b**) a condensation, an ether (**c**) an addition, an ester (**d**) an addition, an ether (**e**) a hydrolysis, a ketone

SAE 24.17 Name the compound formed in the condensation reaction between propionic acid and methanol. (**a**) methyl propionate (**b**) hexanoate (**c**) butyl methanoate (**d**) propyl methanoate

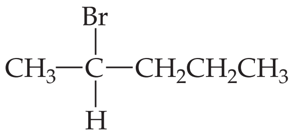
SAE 24.18 Which of the following substances is an ester? (**a**) 3-pentanone (**b**) 1-propylamine (**c**) ethyl acetate (**d**) propanal (**e**) formic acid

SAE 24.19 Which of the substances does *not* contain a carbon–oxygen double bond? (**a**) an ester (**b**) an amide (**c**) an amine (**d**) a ketone (**e**) an aldehyde

SAE 24.20 An amide is formed from the condensation reaction of ______ and ______. (**a**) a carboxylic acid, an alcohol (**b**) a carboxylic acid, an amine (**c**) an amine, an alcohol (**d**) an alcohol, an alcohol

24.5 | Chirality in Organic Chemistry

A molecule possessing a nonsuperimposable mirror image is said to be **chiral** (Greek *cheir*, "hand"). (Section 23.4) *Compounds containing carbon atoms with four different attached groups are inherently chiral.* A carbon atom with four different attached groups is called a *chiral center*. For example, consider 2-bromopentane:



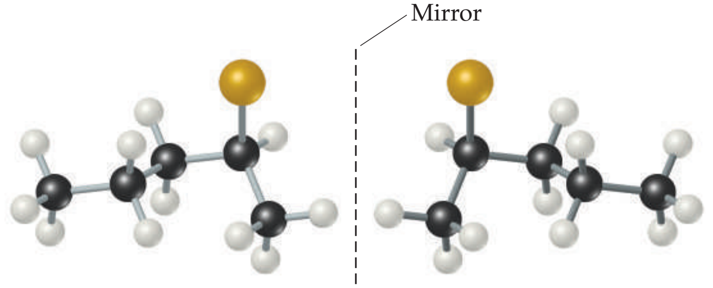
$$CH_3-\underset{H}{\underset{|}{\overset{Br}{\overset{|}{C}}}}-CH_2CH_2CH_3$$

Learning Objective

When you finish Section 24.5, you should be able to:

- Identify organic compounds that are chiral.

Go Figure If you replace Br with CH_3, will the compound be chiral?



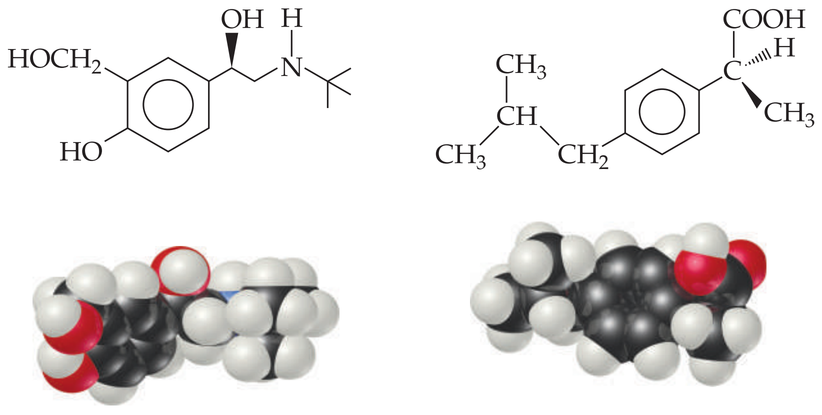
▲ **Figure 24.14 The two enantiomeric forms of 2-bromopentane.** The mirror-image isomers are not superimposable on each other.

All four groups attached to the second carbon are different, making that carbon a chiral center. **Figure 24.14** illustrates the nonsuperimposable mirror images of this molecule. Imagine moving the molecule shown to the left of the mirror over to the right of the mirror. If you then turn it in every possible way, you should see that it cannot be superimposed on the molecule shown to the right of the mirror. Nonsuperimposable mirror images are called either *optical isomers* or *enantiomers*. (Section 23.4) Organic chemists use the labels *R* and *S* to distinguish the two forms. We will not go into the rules for deciding these labels.

The two members of an enantiomer pair have identical physical properties and identical chemical properties when they react with nonchiral reagents. Only in a chiral environment do they behave differently from each other. One interesting property of chiral substances is that their solutions may rotate the plane of polarized light, as explained in Section 23.4.

Chirality is common in organic compounds. It is often not observed, however, because when a chiral substance is synthesized in a typical reaction, the two enantiomers are formed in precisely the same quantity. The resulting mixture is called a *racemic mixture*, and it does not rotate the plane of polarized light because the two forms rotate the light to equal extents in opposite directions. (Section 23.4)

Many drugs are chiral compounds. When a drug is administered as a racemic mixture, often only one enantiomer has beneficial results. The other is often inert, or nearly so, or may even have a harmful effect. For example, the drug (*R*)-albuterol [**Figure 24.15**(**a**)] is a bronchodilator used to relieve the symptoms of asthma. The enantiomer (*S*)-albuterol is not only ineffective as a bronchodilator it actually counters the effects of (*R*)-albuterol. As another example, the nonsteroidal analgesic ibuprofen is a chiral molecule usually sold as the racemic mixture. However, a preparation consisting of just the more active enantiomer, (*S*)-ibuprofen [Figure 24.15(**b**)], relieves pain and reduces inflammation more rapidly than the racemic mixture. For this reason, the chiral version of the drug may in time come to replace the racemic one.



(a) (*R*)-Albuterol **(b)** (*S*)-Ibuprofen

▲ **Figure 24.15 (*R*)-Albuterol and (*S*)-ibuprofen.** (**a**) (*R*)-Albuterol, which acts as a bronchodilator in patients with asthma, is one member of an enantiomer pair. The other member, (*S*)-albuterol, has the OH group pointing down and does not have the same physiological effect. (**b**) For relieving pain and reducing inflammation, the ability of the (*S*) enantiomer of ibuprofen far exceeds that of the (*R*) isomer. In the (*R*) isomer, the positions of the H and CH_3 group on the far-right carbon are switched.

Self-Assessment Exercises

SAE 24.21 Which of the following statements is or are *true*?

(i) To be chiral, an organic molecule must have a carbon atom with four different groups attached to it.
(ii) To be chiral, an organic molecule must contain atoms other than C and H.
(iii) The two enantiomers of a chiral molecule are mirror images of one another.

(**a**) only i (**b**) both i and ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true.

SAE 24.22 Draw out the structural formulas of the following organic compounds and use those drawings to determine which, if any, are chiral.

(i) 2-chloro-3-methylpentane
(ii) 2-bromo-2-chloropropane
(iii) 1-fluoro-2-chloropropane

(**a**) only i (**b**) both i and iii (**c**) both i and ii (**d**) both ii and iii (**e**) All three are chiral.

24.6 | Proteins

The functional groups discussed in Section 24.4 generate a vast array of molecules with very specific chemical reactivities. Nowhere is this specificity more apparent than in *biochemistry*—the chemistry of living organisms. The remainder of this chapter focuses on organic compounds that play a prominent role in plants, animals, fungi, and single-celled organisms like bacteria.

As we move through the major classes of biomolecules, you will see some patterns emerging. Hydrogen bonding (Section 11.2), for example, is critical to the function of many biochemical systems, and the geometry of molecules (Section 9.1) can govern their biological importance and activity. Many of the large molecules in living systems are polymers (Section 12.6) of much smaller molecules. These **biopolymers** can be classified into three broad categories: *proteins*, *polysaccharides* (carbohydrates), and *nucleic acids*. *Lipids* are another common class of molecules in living systems, but they are usually large molecules, not biopolymers.

Learning Objectives

When you finish Section 24.6, you should be able to:

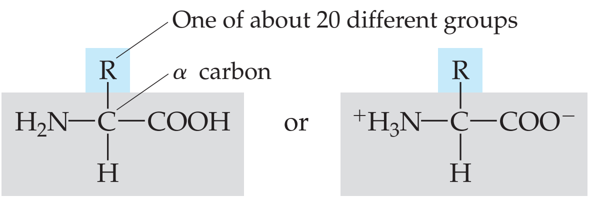
- Describe the features that are common to all amino acids as well as those that differentiate one amino acid from another.
- Interconvert between the structural formula and the name of a peptide or polypeptide.
- Analyze the structures of proteins, differentiating between primary, secondary, tertiary, and quaternary features of the structure.

Amino Acids

Proteins are macromolecules present in all living cells. About 50% of your body's dry mass is protein. Some proteins are structural components in animal tissues; they are a key part of skin, nails, cartilage, and muscles. Other proteins catalyze reactions, transport oxygen, serve as hormones to regulate specific body processes, and perform other tasks. To understand proteins, we must first become familiar with *amino acids*, the small molecules from which proteins are built.

An **amino acid** is a molecule containing an amine group, $—NH_2$, and a carboxylic acid group, $—COOH$. The building blocks of all proteins are *α-amino acids*, where the α (alpha) indicates that the amino group is located on the carbon atom immediately adjacent to the carboxylic acid group. Thus, there is always one carbon atom between the amino group and the carboxylic acid group.

The general formula for an α-amino acid is represented by



$$H_2N-\underset{H}{\overset{R}{C}}-COOH \quad \text{or} \quad {}^{+}H_3N-\underset{H}{\overset{R}{C}}-COO^{-}$$

The doubly ionized form, called a *zwitterion*, usually predominates at near-neutral pH values. This form is a result of the transfer of a proton from the carboxylic acid group to the amine group. [See the "Chemistry and Life" box on "The Amphiprotic Behavior of Amino Acids" (Section 16.10)]

Amino acids differ from one another in the nature of their R groups. Twenty-two amino acids occur naturally in proteins, and **Figure 24.16** shows the 20 of these 22 found in humans. Our bodies can synthesize 11 of these 20 amino acids in sufficient amounts for our needs. The other 9 must be ingested and are called *essential amino acids* because they are necessary components of our diet.

The α-carbon atom of the amino acids, which is the carbon between the amino and carboxylate groups, has four different groups attached to it. The amino acids are thus chiral (except for glycine, which has two hydrogens attached to the central carbon). For historical reasons, the two enantiomeric forms of amino acids are often distinguished by

Go Figure Which group of amino acids has a net positive charge at pH 7?

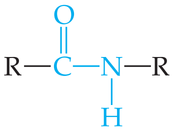
Glutamine (Gln; Q)

▲ **Figure 24.16 The 20 amino acids found in the human body.** The blue screen identifies the different R groups for each amino acid. The acids are shown in the zwitterionic form in which they exist in water at near-neutral pH values. The names shown in bold are the nine essential amino acids that are necessary components of the human diet. Three-letter and one-letter abbreviations for each amino acid are shown in parentheses below its name.

the labels D (from the Latin *dexter*, "right") and L (from the Latin *laevus*, "left"). Nearly all the chiral amino acids found in living organisms have the L configuration at the chiral center. The principal exceptions are the proteins that make up the cell walls of bacteria, which can contain considerable quantities of the D isomers.

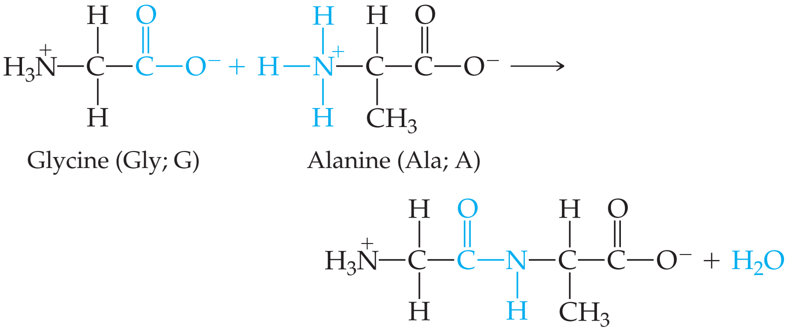
Polypeptides and Proteins

Amino acids are linked together into proteins by amide groups (Table 24.2):



$$R-\overset{O}{\overset{\|}{C}}-\underset{H}{\underset{|}{N}}-R$$

Each amide group is called a **peptide bond** when it is formed by amino acids. A peptide bond is formed by a condensation reaction between the carboxyl group of one amino acid and the amino group of another amino acid. Alanine and glycine, for example, form the dipeptide glycylalanine:



$$H_3\overset{+}{N}-\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-O^- + H-\underset{H}{\underset{|}{\overset{H}{\overset{|}{\overset{+}{N}}}}}-\underset{CH_3}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-O^- \longrightarrow$$

Glycine (Gly; G) Alanine (Ala; A)

$$H_3\overset{+}{N}-\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-\underset{H}{\underset{|}{N}}-\underset{CH_3}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-O^- + H_2O \qquad [24.23]$$

Glycylalanine (Gly–Ala; GA)

The amino acid that furnishes the carboxyl group for peptide-bond formation is named first, with a *-yl* ending; then the amino acid furnishing the amino group is named. Using the abbreviations shown in Figure 24.16, we can abbreviate glycylalanine as either Gly-Ala or GA. In this notation, it is understood that the unreacted amino group is on the left and the unreacted carboxyl group is on the right.

The artificial sweetener *aspartame* (**Figure 24.17**) is the methyl ester of the dipeptide formed from the amino acids aspartic acid and phenylalanine.

Sample Exercise 24.5

Drawing the Structural Formula of a Tripeptide

Draw the structural formula for alanylglycylserine.

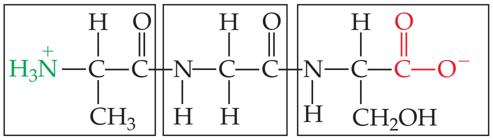
SOLUTION

Analyze We are given the name of a substance with peptide bonds and asked to write its structural formula.

Plan The name of this substance suggests that three amino acids—alanine, glycine, and serine—have been linked together, forming a *tripeptide*. Note that the ending *-yl* has been added to each amino acid except for the last one, serine. By convention, the sequence of amino acids in peptides and proteins is written from the nitrogen end to the carbon end: The first-named amino acid (alanine, in this case) has a free amino group, and the last-named one (serine) has a free carboxyl group.

Solve We first combine the carboxyl group of alanine with the amino group of glycine to form a peptide bond and then the carboxyl group of glycine with the amino group of serine to form another peptide bond:

Amino group → Carboxyl group



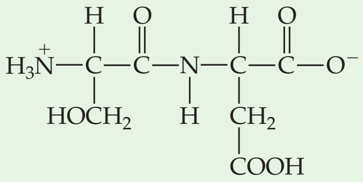
$$H_3\overset{+}{N}-\underset{CH_3}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-\underset{H}{\underset{|}{N}}-\underset{H}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-\underset{H}{\underset{|}{N}}-\underset{CH_2OH}{\underset{|}{\overset{H}{\overset{|}{C}}}}-\overset{O}{\overset{\|}{C}}-O^-$$

Ala Gly Ser
A G S

We can abbreviate this tripeptide as either Ala-Gly-Ser or AGS.

▶ Practice Exercise

Name the dipeptide and give the two ways of writing its abbreviation.



$$\mathrm{H_3\overset{+}{N}{-}\underset{HOCH_2}{\overset{H}{C}}{-}\overset{O}{\overset{\|}{C}}{-}\underset{H}{N}{-}\underset{CH_2COOH}{\overset{H}{C}}{-}\overset{O}{\overset{\|}{C}}{-}O^-}$$

Polypeptides are formed when a large number of amino acids (> 30) are linked together by peptide bonds. Proteins are linear (that is, unbranched) polypeptide molecules with molecular weights ranging from about 6000 to over 50 million amu. Because up to 22 different amino acids are linked together in proteins and because proteins consist of hundreds of amino acids, the number of possible arrangements of amino acids within proteins is virtually limitless.

Protein Structure

The sequence of amino acids from the "N terminus" (that is, the amino end) to the "C terminus" (the carboxylic acid end) along a protein chain is called its **primary structure** and gives the protein its unique identity. A change in even one amino acid can alter the biochemical characteristics of the protein. For example, sickle-cell anemia is a genetic disorder resulting from a single replacement in a protein chain in hemoglobin. The chain that is affected contains 146 amino acids. The substitution of an amino acid with a hydrocarbon side chain for one that has an acidic functional group in the side chain alters the solubility properties of the hemoglobin, and normal blood flow is impeded. [See the "Chemistry and Life" box on "Sickle-Cell Anemia"(Section 13.6)]

Proteins in living organisms are not simply long, flexible chains with random shapes. Rather, the chains self-assemble into structures based on the intermolecular forces we learned about in Chapter 11. This self-assembling leads to a protein's **secondary structure**, which refers to how segments of the protein chain are oriented in a regular pattern, as seen in **Figure 24.18**.

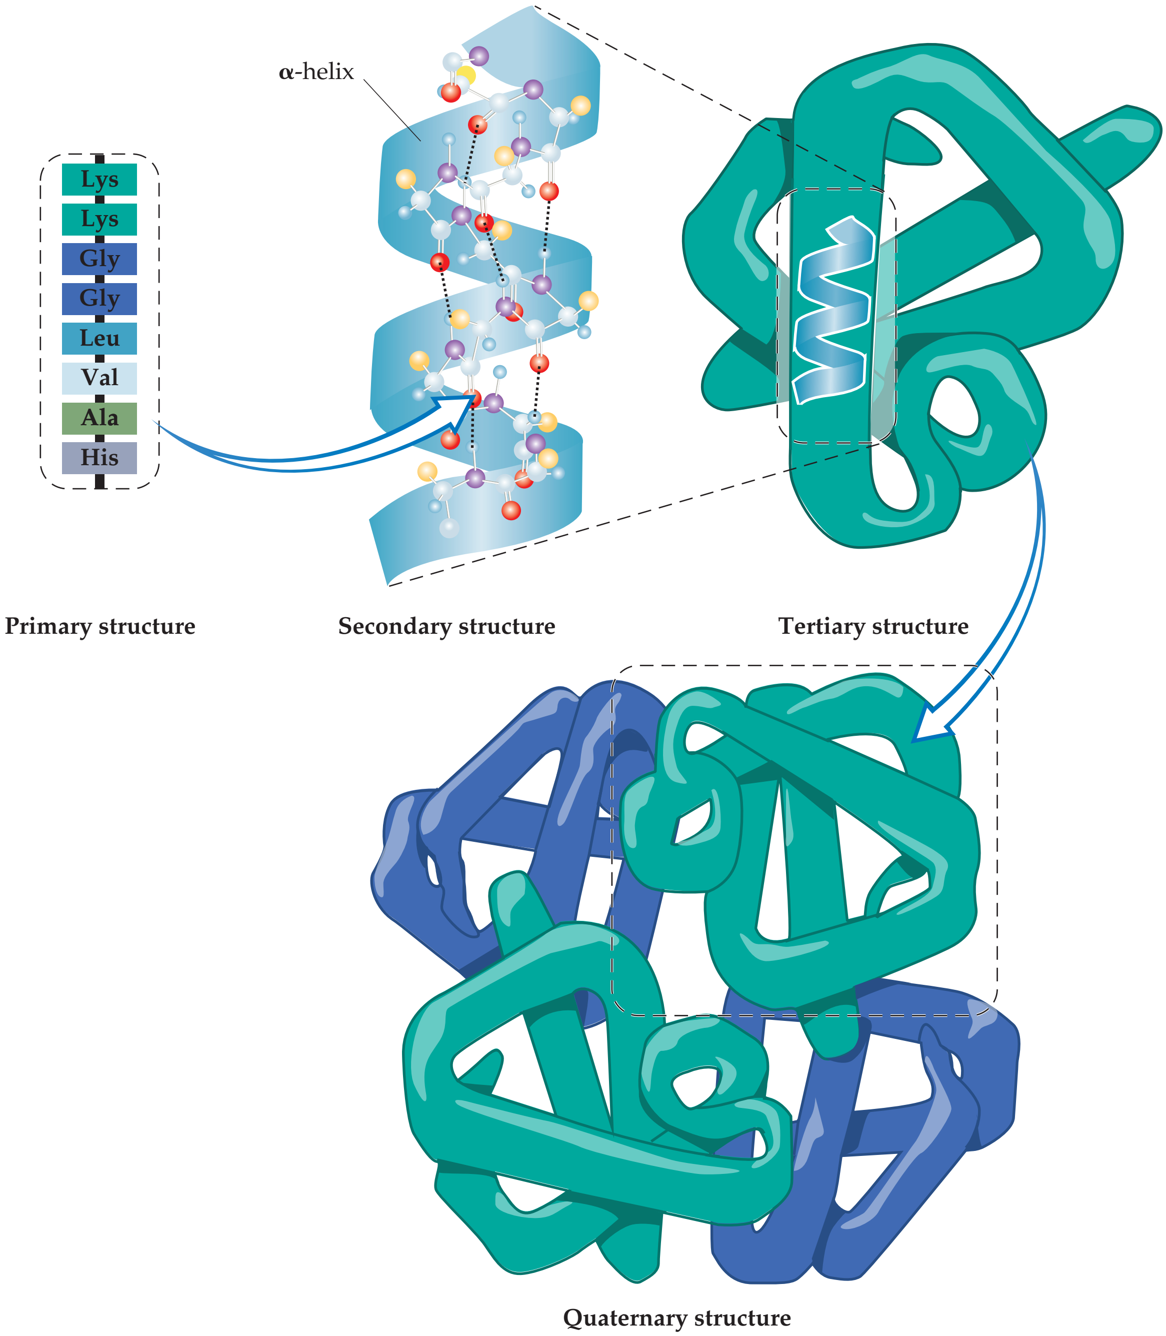
One of the most important and common secondary structure arrangements is the **α-helix** (alpha helix). The alpha helix is held in position by hydrogen bonds between amide H atoms and carbonyl O atoms in the main chain, not the side chains, of the protein. The pitch of the helix and its diameter must be such that (1) no bond angles are strained and (2) the N—H and C═O functional groups on adjacent turns are in proper position for hydrogen bonding. An arrangement of this kind is possible for some amino acids along the chain but not for others. Large protein molecules may contain segments of the chain that have the α-helical arrangement interspersed with sections in which the chain is in a random coil.

The other common secondary structure of proteins is the **β-sheet** (beta sheet). Beta sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand. Like the alpha helix, the hydrogen bonding in beta sheets is between the peptide backbones, not the side chains.

Proteins are not active biologically unless they are in a particular shape in solution. The process by which the protein adopts its biologically active shape is called **folding**. The shape of a protein in its folded form—determined by all the bends, kinks, and sections of rodlike α-helical, β-sheet, or flexible coil components—is called the **tertiary structure**.

Globular proteins fold into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells. They have nonstructural functions, such as combating the invasion of foreign objects, transporting and storing oxygen (hemoglobin and myoglobin), and acting as catalysts. The *fibrous proteins* form a second class of proteins. In these substances, the long coils align more or less in parallel to form long, water-insoluble fibers. Fibrous proteins provide structural integrity and strength to many kinds of tissue and are the main components of muscle, tendons, and hair. The largest known proteins, in excess of 27,000 amino acids long, are muscle proteins.

The tertiary structure of a protein is maintained by many different interactions. Certain foldings of the protein chain lead to lower-energy (more stable) arrangements than



▲ **Figure 24.18 The four levels of protein structure.** Amino acids, linked by amide bonds from the amine end to the acid end, can hydrogen-bond to form alpha helix or beta sheet secondary structures. These secondary structures fold into tertiary structures based on electrostatic and van der Waals interactions. Many proteins form quaternary structures in which multiple protein molecules associate to form dimers, trimers, or tetramers (as shown here).

do other folding patterns. For example, a globular protein dissolved in aqueous solution folds in such a way that the nonpolar hydrocarbon portions are tucked within the molecule, away from the polar water molecules. Most of the more polar acidic and basic side chains, however, project into the solution, where they can interact with water molecules through ion–dipole, dipole–dipole, or hydrogen-bonding interactions.

Some proteins are assemblies of more than one polypeptide chain. Each chain has its own tertiary structure, and two or more of these tertiary subunits may aggregate into a larger functional macromolecule. The way the tertiary subunits are arranged is called the **quaternary structure** of the protein (Figure 24.18). For example, hemoglobin, the oxygen-carrying protein of red blood cells, consists of four tertiary subunits. Each subunit contains a component called a heme with an iron atom that binds oxygen as depicted in Figure 23.15. The quaternary structure is maintained by the same types of interactions that maintain the tertiary structure.

One of the most fascinating current hypotheses in biochemistry is that misfolded proteins can cause infectious disease. These infectious misfolded proteins are called *prions*. The best example of a prion is the one thought to be responsible for mad cow disease, which can be transmitted to humans.

Self-Assessment Exercises

SAE 24.23 Which chemical line structure represents an amino acid, where R is one of 20 side chains? (**a**) $H_2N-CHR-COOH$ (**b**) H_2N-CH_2-COOR (**c**) $HOOC-CH_2-CHR-NH_2$ (**d**) $HOOC-R-NH_2$

SAE 24.24 Which of the following statements about amino acids is or are *true*?

(**i**) All amino acids are chiral.
(**ii**) All amino acids have a net charge at pH 7.
(**iii**) Some amino acids are acidic and some are basic.

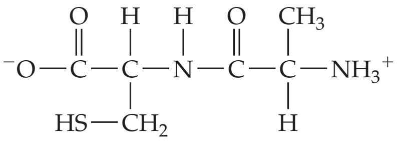
(**a**) only i (**b**) only ii (**c**) only iii (**d**) both i and iii (**e**) All three statements are true.

SAE 24.25 Which of the following statements about the peptide bond is or are *true*?

(**i**) Peptide bonds are formed from the hydrolysis reactions of amino acids.
(**ii**) The peptide bond contains a carbonyl group.
(**iii**) Any amino acid can make a peptide bond with either its amine group or its acid group.

(**a**) only i (**b**) only ii (**c**) only iii (**d**) both ii and iii (**e**) All three statements are true.

SAE 24.26 What is the name of the dipeptide shown here?



(**a**) glycylmethionine (G–A) (**b**) methionylalanine (M–A) (**c**) alanylcysteine (A–C) (**d**) cysteinylalanine (C–A) (**e**) alanylmethionine (A–M)

SAE 24.27 Hydrogen bonds play the dominant role in what aspect of a protein's structure? (**a**) primary structure (**b**) secondary structure (**c**) tertiary structure (**d**) quaternary structure

24.7 | Carbohydrates

Learning Objectives

When you finish Section 24.7, you should be able to:

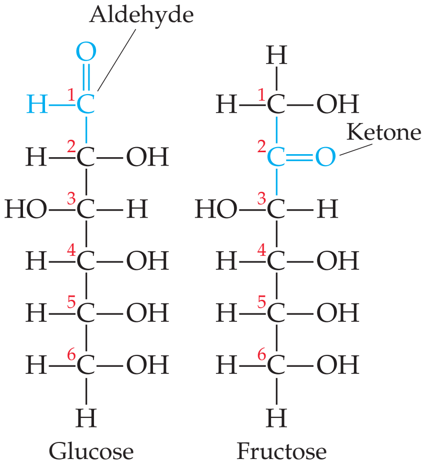
- Identify organic compounds that are carbohydrates from their molecular formula, structural formula, or condensed structural formula.
- Differentiate monosaccharides, disaccharides, and polysaccharides, and list common examples of each.

Carbohydrates are an important class of naturally occurring substances found in both plant and animal matter. The name **carbohydrate** ("hydrate of carbon") comes from the empirical formulas for most substances in this class, which can be written as $C_x(H_2O)_y$. For example, **glucose**, the most abundant carbohydrate, has the molecular formula $C_6H_{12}O_6$, or $C_6(H_2O)_6$. Carbohydrates are not really hydrates of carbon; rather, they are polyhydroxy aldehydes and ketones. Glucose, for example, is a six-carbon aldehyde sugar, whereas *fructose*, the sugar that occurs widely in fruit, is a six-carbon ketone sugar (**Figure 24.19**).

The glucose molecule, having both alcohol and aldehyde functional groups and a reasonably long and flexible backbone, can form a six-member-ring structure, as shown in **Figure 24.20**. In fact, in an aqueous solution only a small percentage of the glucose molecules are in the open-chain form. Although the ring is often drawn as if it were planar, the molecules are actually nonplanar because of the tetrahedral bond angles around the C and O atoms of the ring.

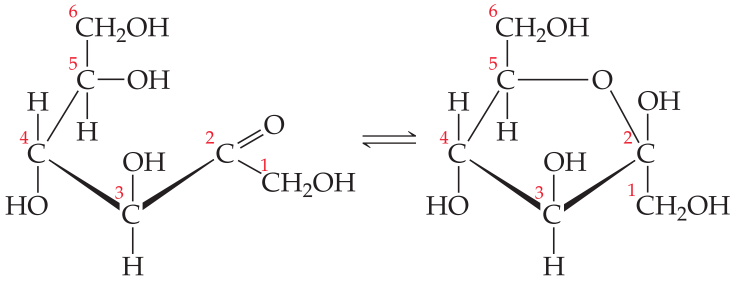
Figure 24.20 shows that the ring structure of glucose can have two relative orientations. In the α form, the OH group on C1 and the CH_2OH group on C5 point in *opposite* directions, whereas in the β form, they point in the *same* direction. Although the difference between the α and β forms might seem small, it has enormous biological consequences, including the vast difference in properties between starch and cellulose.

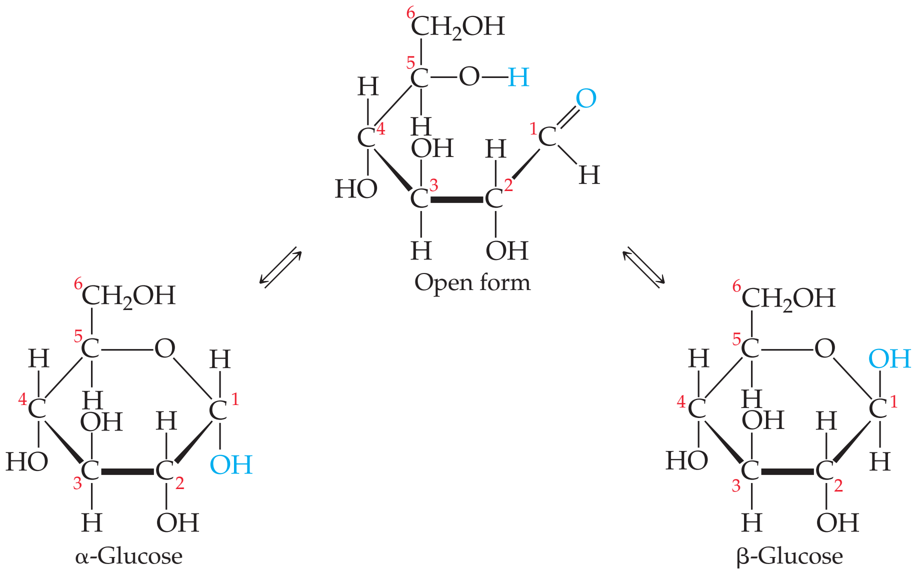
Fructose can cyclize to form either five- or six-member rings. The five-member ring forms when the C5 hydroxyl group reacts with the C2 carbonyl group:



Glucose Fructose

▲ **Figure 24.19** **Linear structure of the carbohydrates glucose and fructose.**





▲ **Figure 24.20 Cyclic glucose has an α form and a β form.**

The six-member ring results from the reaction between the C6 hydroxyl group and the C2 carbonyl group.

Sample Exercise 24.6

Identifying Functional Groups and Chiral Centers in Carbohydrates

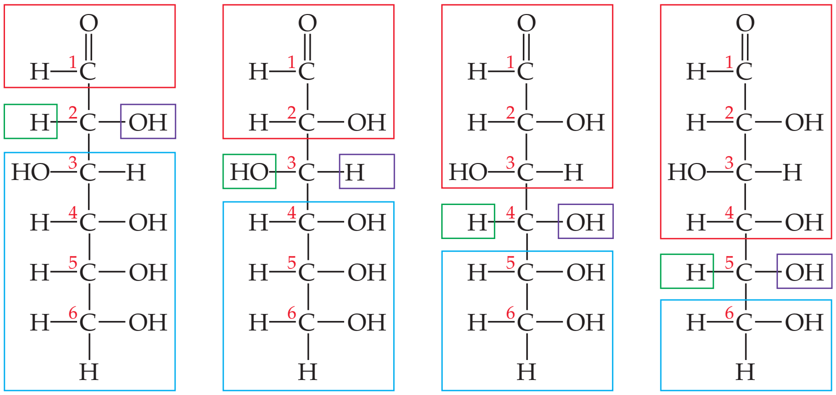
How many chiral carbon atoms are there in the open-chain form of glucose (Figure 24.19)?

SOLUTION

Analyze We are given the structure of glucose and asked to determine the number of chiral carbons in the molecule.

Plan A chiral carbon has four different groups attached (Section 24.5). We need to identify those carbon atoms in glucose.

Solve Carbons 2, 3, 4, and 5 each have four different groups attached to them:



Thus, there are four chiral carbon atoms in the glucose molecule.

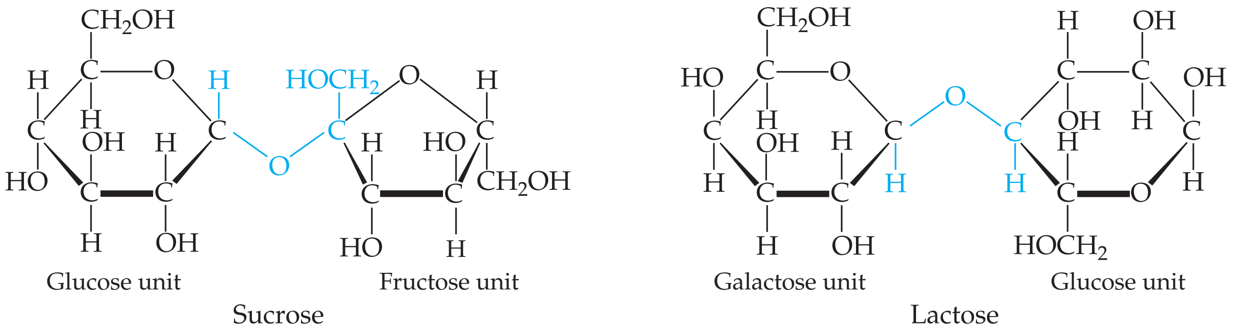
▶ **Practice Exercise**

Name the functional groups present in the beta form of glucose.

Disaccharides

Both glucose and fructose are examples of **monosaccharides**, simple sugars that cannot be broken into smaller molecules by hydrolysis with aqueous acids. Two monosaccharide units can be linked together by a condensation reaction to form a **disaccharide**. The structures of two common disaccharides, *sucrose* (table sugar) and *lactose* (milk sugar), are shown in **Figure 24.21**.

The word *sugar* makes us think of sweetness. All sugars are sweet, but they differ in the degree of sweetness we perceive when we taste them. Sucrose is about six times sweeter than lactose, slightly sweeter than glucose, but only about half as sweet as fructose. Disaccharides



▲ **Figure 24.21 Two disaccharides.**

can be reacted with water (hydrolyzed) in the presence of an acid catalyst to form monosaccharides. When sucrose is hydrolyzed, the mixture of glucose and fructose that forms, called *invert sugar*,* is sweeter to the taste than the original sucrose. The sweet syrup present in canned fruits and candies is largely invert sugar formed from hydrolysis of added sucrose.

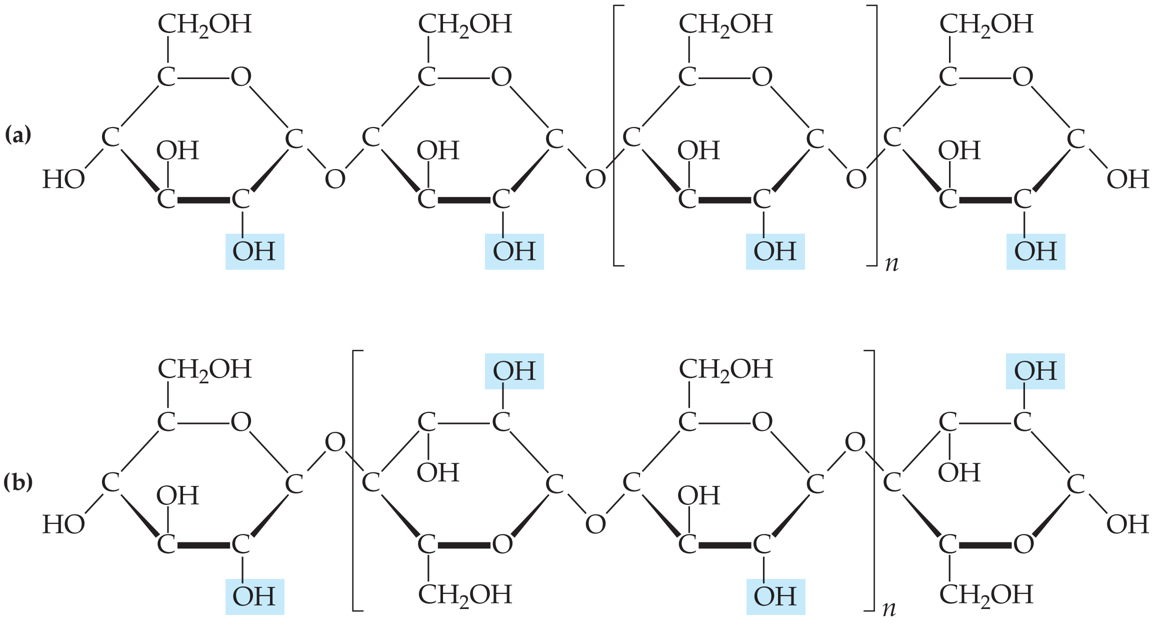
Polysaccharides

Polysaccharides are made up of many monosaccharide units joined together. The most important polysaccharides are starch, glycogen, and cellulose, all three of which are formed from repeating glucose units.

Starch is not a pure substance. The term refers to a group of polysaccharides found in plants. Starches serve as a major method of food storage in plant seeds and tubers. Corn, potatoes, wheat, and rice all contain substantial amounts of starch. These plant products serve as major sources of needed food energy for humans. Enzymes in the digestive system catalyze the hydrolysis of starch to glucose.

Some starch molecules are unbranched chains, whereas others are branched. Figure 24.22(**a**) illustrates an unbranched starch structure. Notice, in particular, that the glucose units are in the α form, with the bridging oxygen atoms pointing in one direction and the CH_2OH groups pointing in the opposite direction.

Glycogen is a starch-like substance synthesized in the animal body. Glycogen molecules vary in molecular weight from about 5000 to more than 5 million amu. Glycogen acts as a kind of energy bank in the body. It is concentrated in the muscles and liver. In



▲ **Figure 24.22 Structures of (a) starch and (b) cellulose.** Not all hydrogen atoms are shown.

---

*The term *invert sugar* comes from the fact that rotation of the plane of polarized light by the glucose-fructose mixture is in the opposite direction, or inverted, from that of the sucrose solution.

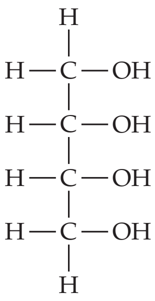
muscles, it serves as an immediate source of energy; in the liver, it serves as a storage place for glucose and helps to maintain a constant glucose level in the blood.

Cellulose [Figure 24.22(**b**)] forms the major structural unit of plants. Wood is about 50% cellulose; cotton fibers are almost entirely cellulose. Cellulose consists of an unbranched chain of glucose units, with molecular weights averaging more than 500,000 amu. At first glance, this structure looks very similar to that of starch. In cellulose, however, the glucose units are in the β form, with each bridging oxygen atom pointing in the same direction as the CH_2OH group in the ring to its left.

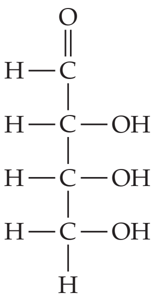
Because the individual glucose units have different relationships to one another in starch and cellulose, enzymes that readily hydrolyze starches do not hydrolyze cellulose. Thus, you might eat a kilogram of cellulose and receive no caloric value from it, even though the heat of combustion per unit mass is essentially the same for both cellulose and starch. A kilogram of starch, in contrast, would represent a substantial caloric intake. The difference is that the starch is hydrolyzed to glucose, which is eventually oxidized with the release of energy. However, enzymes in the body do not readily hydrolyze cellulose, so it passes through the digestive system relatively unchanged. Many bacteria contain enzymes, called cellulases, that hydrolyze cellulose. These bacteria are present in the digestive systems of grazing animals, such as cattle, that use cellulose for food.

Self-Assessment Exercises

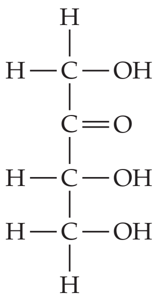
SAE 24.28 Which of the compounds shown here are carbohydrates?



(i)



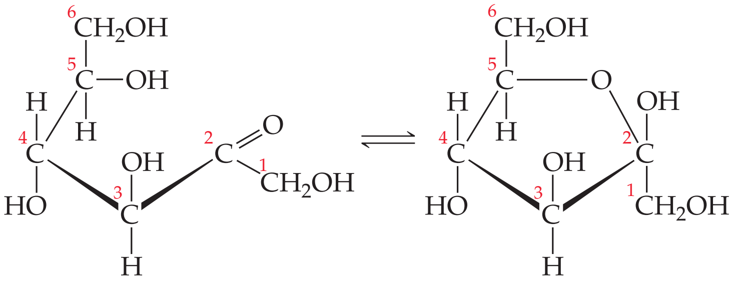
(ii)



(iii)

(**a**) only i (**b**) only ii (**c**) only iii (**d**) both ii and iii (**e**) All three molecules are carbohydrates.

SAE 24.29 The open form and one possible ring form of fructose are shown here:



Both forms have hydroxy groups, just like alcohols. We can further specify the functional groups in each molecule by noting that the open form is ______ and the ring form is ______. (**a**) an aldehyde, an aldehyde (**b**) an aldehyde, an ether (**c**) a ketone, a ketone (**d**) a ketone, an ester (**e**) a ketone, an ether

SAE 24.30 Which of the following compounds is a disaccharide? (**a**) glucose (**b**) sucrose (**c**) fructose (**d**) cellulose (**e**) starch

SAE 24.31 What is the relationship between the monosaccharides glucose and fructose (see Figure 24.19 for drawings of the open forms of these two molecules)?

(**a**) The two molecules are structural isomers.
(**b**) The two molecules are geometric isomers.
(**c**) The two molecules are optical isomers.
(**d**) The two molecules are not isomers.

24.8 | Lipids

Learning Objectives

When you finish Section 24.8, you should be able to:

- Describe the characteristic features of lipids.
- Distinguish various types of lipids from one another, including saturated fats, unsaturated fats, fatty acids, and phospholipids.

Lipids are a diverse class of nonpolar biological molecules used by organisms for long-term energy storage (fats, oils) and as elements of biological structures (phospholipids, cell membranes, waxes).

Fats

Fats are lipids derived from glycerol and fatty acids. Glycerol is an alcohol with three OH groups. Fatty acids are carboxylic acids (RCOOH) in which R is a hydrocarbon chain, usually 15 to 19 carbon atoms in length. Glycerol and fatty acids undergo condensation reactions to form ester linkages as shown in **Figure 24.23**. Three fatty acid molecules join to a glycerol. Although the three fatty acids in a fat can be the same, as they are in Figure 24.23, it is also possible that a fat contains three different fatty acids.

Lipids with saturated fatty acids are called saturated fats and are commonly solids at room temperature (such as butter and shortening). Unsaturated fats contain one or more double bonds in their carbon–carbon chains. The cis and trans nomenclature we learned for alkenes applies: Trans fats have H atoms on the opposite sides of the C═C double bond, whereas cis fats have H atoms on the same sides of the C═C double bond. Unsaturated fats (such as olive oil and peanut oil) are usually liquid at room temperature and are more often found in plants. For example, the major component (approximately 60 to 80%) of olive oil is oleic acid, *cis*-$CH_3(CH_2)_7CH{=}CH(CH_2)_7COOH$. Oleic acid is an example of a *monounsaturated* fatty acid, meaning it has only one carbon–carbon double bond in the chain. In contrast, *polyunsaturated* fatty acids have more than one carbon–carbon double bond in the chain.

For humans, trans fats are not nutritionally required, which is why some governments are moving to ban them in foods. How, then, do trans fats end up in our food? The process that converts unsaturated fats (such as oils) into saturated fats (such as shortening) is hydrogenation. (Section 24.3) The by-products of this hydrogenation process include trans fats.

Some of the fatty acids essential for human health must be available in our diets because our metabolism cannot synthesize them. These essential fatty acids are ones that have the carbon–carbon double bonds either three carbons or six carbons away from the $—CH_3$ end of the chain. These are called omega-3 and omega-6 fatty acids, where *omega* refers to the last carbon in the chain (the carboxylic acid carbon is considered the first, or alpha, one).

▲ **Figure 24.24 Structure of a phospholipid and a cell membrane.** Living cells are encased in membranes typically made of phospholipid bilayers. The bilayer structure is stabilized by the favorable interactions of the hydrophobic tails of the phospholipids, which point away from both the water inside the cell and the water outside the cell, while the charged head groups face the two water environments.

Phospholipids

Phospholipids are similar in chemical structure to fats but have only two fatty acids attached to a glycerol. The third alcohol group of glycerol is joined to a phosphate group (**Figure 24.24**). The phosphate group can also be attached to a small charged or polar group, such as choline, as shown in the figure. The diversity in phospholipids is based on differences in their fatty acids and in the groups attached to the phosphate group.

In water, phospholipids cluster together, with their charged polar heads facing the water and their nonpolar tails facing inward. The phospholipids thus form a bilayer that is a key component of cell membranes (Figure 24.24).

Self-Assessment Exercises

SAE 24.32 When glycerol and a fatty acid undergo a _____ reaction, the products are a _____ and water? (**a**) condensation, fat (**b**) condensation, phospholipid (**c**) hydrogenation, fat (**d**) hydrogenation, phospholipid (**e**) hydrolysis, fat

SAE 24.33 Which of the following statements about lipids is or are *true*?

(**i**) Unsaturated fats contain both C=C and C=O double bonds.
(**ii**) Cell membranes are made from fatty acids.
(**iii**) Saturated fats can be further subdivided into trans and cis fats.

(**a**) only i (**b**) only ii (**c**) only iii (**d**) both i and ii (**e**) both ii and iii

24.9 | Nucleic Acids

Learning Objectives

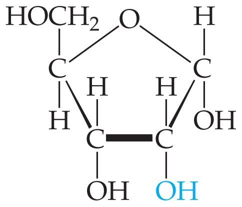
When you finish Section 24.9, you should be able to:

- Describe the composition and structures of nucleic acids, in both the single-strand and double-helix forms.
- Explain the differences between deoxyribonucleic acids (DNAs) and ribonucleic acids (RNAs).
- Determine the sequence of bases that are complementary on two strands of DNA or RNA, and describe the process of DNA replication.

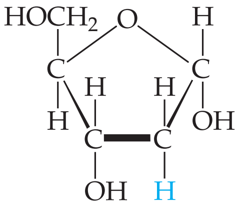
Nucleic acids are a class of biopolymers that are the chemical carriers of an organism's genetic information. **Deoxyribonucleic acids (DNAs)** are huge molecules whose molecular weights may range from 6 to 16 million amu. **Ribonucleic acids (RNAs)** are smaller molecules, with molecular weights in the range of 20,000 to 40,000 amu. Whereas DNA is found primarily in the nucleus of the cell, RNA is found mostly outside the nucleus in the *cytoplasm*, the nonnuclear material enclosed by the cell membrane. DNA stores the genetic information of the cell and specifies which proteins the cell can synthesize. RNA carries the information stored by DNA out of the cell nucleus into the cytoplasm, where the information is used in protein synthesis.

The monomers of nucleic acids, called **nucleotides**, are formed from a five-carbon sugar, a nitrogen-containing organic base, and a phosphate group. An example is shown in Figure 24.25.

The five-carbon sugar in RNA is *ribose*, and that in DNA is *deoxyribose*:



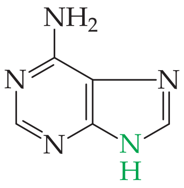
Ribose



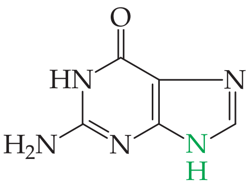
Deoxyribose

Deoxyribose differs from ribose only in having one fewer oxygen atom at carbon 2.

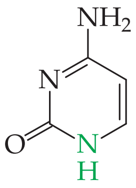
There are five nitrogen-containing bases in nucleic acids:



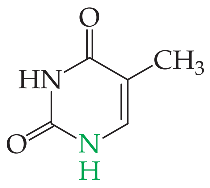
Adenine (A)
DNA
RNA



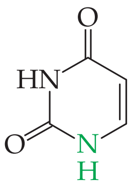
Guanine (G)
DNA
RNA



Cytosine (C)
DNA
RNA



Thymine (T)
DNA



Uracil (U)
RNA

The first three bases shown here are found in both DNA and RNA. Thymine occurs only in DNA, whereas uracil occurs only in RNA. In either nucleic acid, each base is attached to a five-carbon sugar through a bond to the nitrogen atom shown in color.

◀ **Figure 24.26 A polynucleotide.** Because the sugar in each nucleotide is deoxyribose, this polynucleotide is DNA.

The nucleic acids RNA and DNA are *polynucleotides* formed by condensation reactions between a phosphoric acid OH group on one nucleotide and a sugar OH group on another nucleotide. Thus, the polynucleotide strand has a backbone consisting of alternating sugar and phosphate groups with the bases extending off the chain as side groups (**Figure 24.26**). The carbons in the sugars are numbered 1′, 2′, and so forth, as shown in Figure 24.26. Just as proteins have a sequence of amino acids from the N terminus to the C terminus, nucleic acids have a sequence of bases that start from the 5′ end of the sugar–phosphate backbone and go to the 3′ end.

The DNA strands wind together in an antiparallel **double helix** [**Figure 24.27**(**a**)]. The two strands are held together by attractions between bases (represented by T, A, C, and G). These attractions involve dispersion forces, dipole–dipole forces, and hydrogen bonds. (Section 11.2) As shown in Figure 24.27(**b**), the structures of thymine and adenine

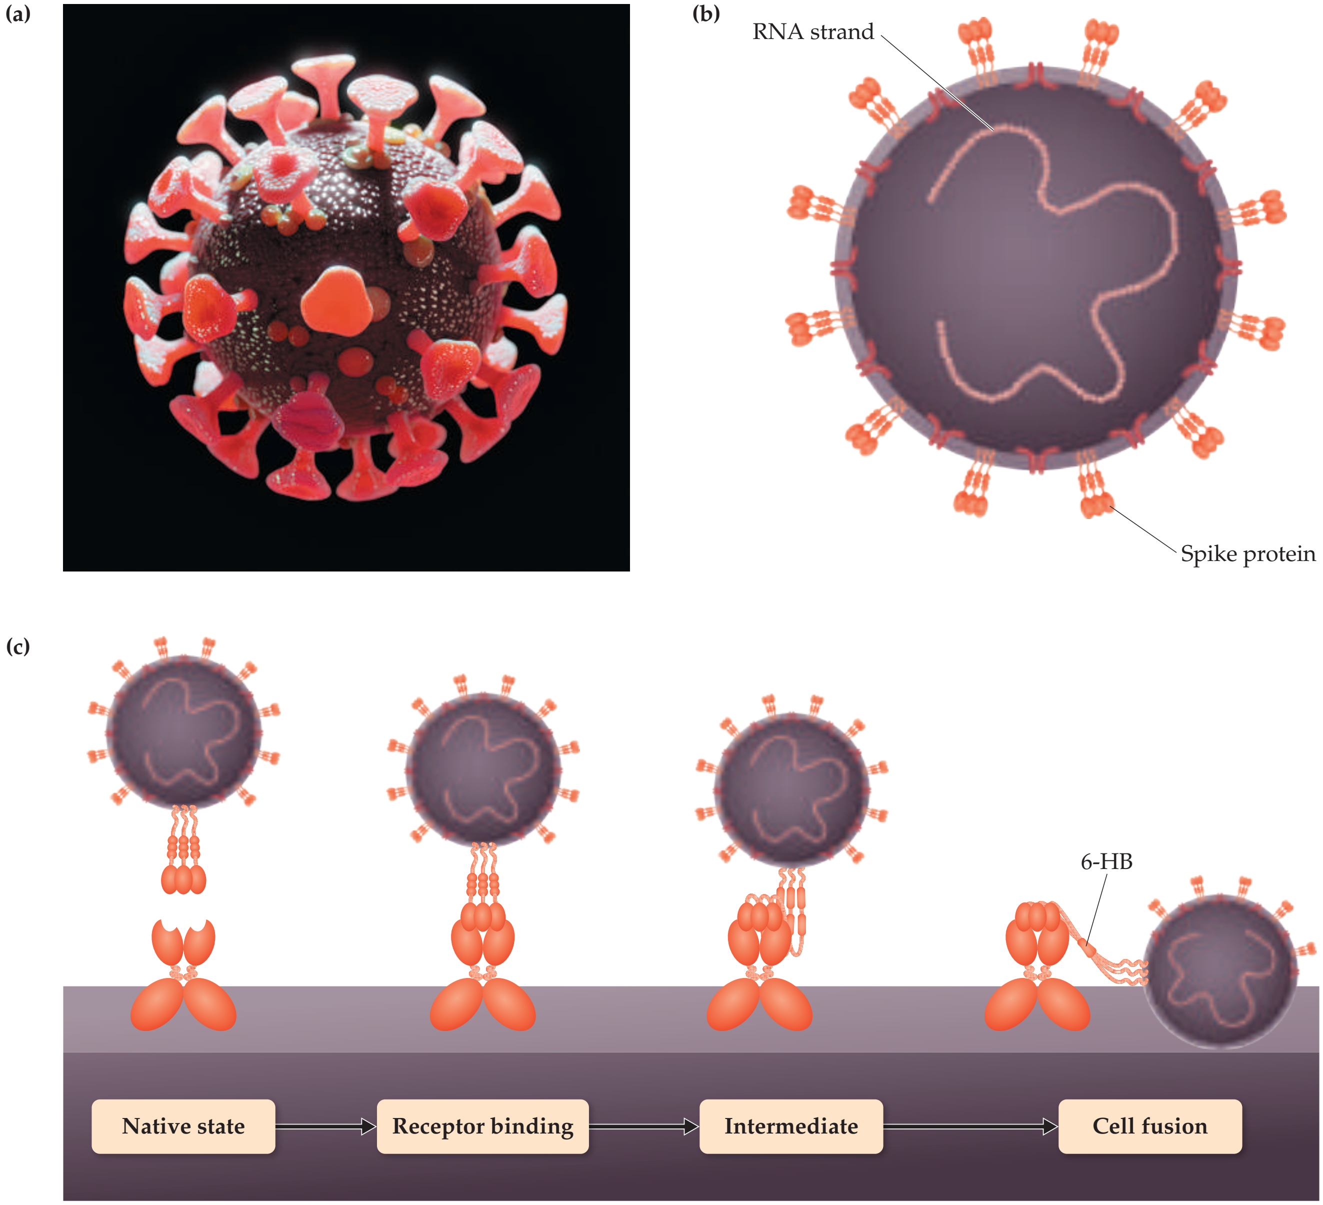
CHEMISTRY AND LIFE COVID-19 Vaccines

In 2019, a virus known as SARS-CoV-2 was first reported in humans. This virus led to the disease known as COVID-19, which to date has killed millions of people on the planet. This virus consists of a single strand of RNA, approximately 30,000 nucleotides long, enveloped in a protein coat (**Figure 24.28**). There are three types of protein on the surface of the SARS-CoV-2 virus, which are referred to as the spike (S), membrane (M), and envelope (E) proteins. The S protein is the one that recognizes a common protein on the cell membrane of the host, docks the virus there, and then fuses the virus with the cell membrane. Once inside the cell, the virus uses the host's cellular machinery to replicate its RNA over and over.

Understanding how this virus works has been key to developing vaccines to combat it. The current Pfizer-BioNTech and Moderna vaccines are based on a type of RNA called messenger RNA or mRNA for short. mRNA is a single-stranded RNA molecule that is complementary to a strand of DNA that codes for a specific gene. Normally, the mRNA molecules are made in the cell nucleus and then migrate into the cytoplasm, where the translation machinery of the cell binds to them, reads the code on the mRNA, and makes a specific protein.

Both the Pfizer-BioNTech and Moderna vaccines contain mRNA molecules that carry the instructions to produce a modified spike protein. In the vaccine, the mRNA is mixed with lipids and salts to stabilize it. Once injected, the body's cells take up the mRNA and produce the modified spike protein, which is subsequently displayed on the surface of the cell. The modified protein contains proline residues in certain spots that make the protein look like it has just bound to the outer surface of the cell membrane but has not yet fused with the membrane. The immune system detects these modified (and harmless) versions of the spike protein and generates antibodies against it. These antibodies, large proteins themselves, circulate in the body ready to combat real SARS-CoV-2 viruses that may enter the body, thereby providing immunity.



▲ **Figure 24.28 The SARS-CoV-2 virus.** (**a**) A microscopic image of the virus where the spike proteins on the surface are clearly visible. (**b**) A schematic view of the virus. (**c**) The mechanism by which the virus docks and then penetrates the cell membrane to release its RNA into the cell.

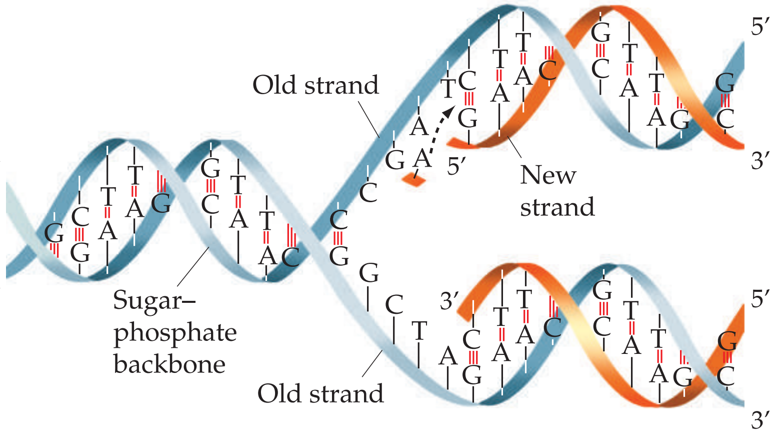
The traditional approach to vaccines is to introduce either dead/inactivated virus cells or weakened virus cells to trigger an immune response. The Sinovac and Sinopharm COVID-19 vaccines, developed in China, take this approach by using inactivated SARS-CoV-2 virus cells. The Johnson & Johnson (Jannsen) vaccine uses yet another approach, called a virus vector, to provoke an immune response. In this technology, a piece of DNA encoded with instructions to create modified spike protein is embedded inside an unrelated virus (a virus similar to the one that causes the common cold). The virus delivers this piece of DNA to your cells upon which the cell machinery builds modified spike proteins. From there the process unfolds very much as it does with the mRNA vaccines.

The COVID-19 vaccines were developed at an unprecedentedly rapid pace. Most vaccines take 10–15 years to develop, test, and gain all the necessary government approvals. The fastest vaccination development prior to the outbreak of COVID-19 was the mumps vaccine, which was developed in the 1960s in a mere 4 years. The rapid development and effectiveness of mRNA and viral vector vaccines to protect against this deadly disease are a triumph of modern science, built upon decades of fundamental biochemical research that has saved countless lives.

make them perfect partners for hydrogen bonding. Likewise, cytosine and guanine form ideal hydrogen-bonding partners. We say that thymine and adenine are *complementary* to each other and cytosine and guanine are *complementary* to each other. In the double-helix structure, therefore, each thymine on one strand is opposite an adenine on the other strand, and each cytosine is opposite a guanine. The double-helix structure with complementary bases on the two strands is the key to understanding how DNA functions.

The two strands of DNA unwind during cell division, and new complementary strands are constructed on the unraveling strands (**Figure 24.29**). This process results in two identical double-helix DNA structures, each containing one strand from the original structure and one new strand. This replication allows genetic information to be transmitted when cells divide.

The structure of DNA is also the key to understanding protein synthesis, the means by which viruses infect cells, and many other problems of central importance to modern biology. These themes are beyond the scope of this book. If you take courses in the life sciences, however, you will learn a good deal about such matters.



▲ **Figure 24.29 DNA replication.** The original DNA double helix partially unwinds, and new nucleotides line up on each strand in complementary fashion. Hydrogen bonds help align the new nucleotides with the original DNA chain. When the new nucleotides are joined by condensation reactions, two identical double-helix DNA molecules result.

Self-Assessment Exercises

SAE 24.34 Which of the following molecular fragments is *not* part of the structure of a nucleic acid? (**a**) nitrogen-containing base (**b**) amino acid (**c**) phosphate group (**d**) a sugar ring containing five carbon atoms

SAE 24.35 Which base is found in RNA but not in DNA? (**a**) adenine (**b**) guanine (**c**) cytosine (**d**) thymine (**e**) uracil

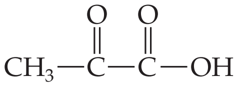
SAE 24.36 Which of the following statements describing the structure and/or function of RNA is *false*?

(**a**) RNA is found primarily inside the cell nucleus.
(**b**) RNA carries information stored by DNA.
(**c**) RNA is used in protein synthesis.
(**d**) RNA is generally a smaller molecule than DNA.
(**e**) The sugar rings in RNA have an additional hydroxyl group compared to the sugar rings in DNA.

SAE 24.37 A short strand of DNA is found to have the sequence 5′–TTGCA–3′. What is the sequence of the complementary DNA strand? (**a**) 3′–TTGCA–5′ (**b**) 3′–TTGGG–5′ (**c**) 3′–GGATC–5′ (**d**) 3′–AACGT–5′

Putting Concepts Together

Pyruvic acid,



$$CH_3-\overset{\overset{\displaystyle O}{\|}}{C}-\overset{\overset{\displaystyle O}{\|}}{C}-OH$$

is formed in the body from carbohydrate metabolism. In muscles, it is reduced to lactic acid in the course of exertion. The acid-dissociation constant for pyruvic acid is 3.2×10^{-3}. (**a**) Why does pyruvic acid have a larger acid-dissociation constant than acetic acid? (**b**) Would you expect pyruvic acid to exist primarily as the neutral acid or as dissociated ions in muscle tissue, assuming a pH of 7.4 and an initial acid concentration of 2×10^{-4} *M*? (**c**) What would you predict for the solubility properties of pyruvic acid? Explain. (**d**) What is the hybridization of each carbon atom in pyruvic acid? (**e**) Assuming H atoms as the reducing agent, write a balanced chemical equation for the reduction of pyruvic acid to lactic acid (Figure 24.13). (Although H atoms do not exist as such in biochemical systems, biochemical reducing agents deliver hydrogen for such reductions.)

SOLUTION

(**a**) The acid-dissociation constant for pyruvic acid should be somewhat greater than that of acetic acid because the carbonyl function on the α-carbon atom of pyruvic acid exerts an electron-withdrawing effect on the carboxylic acid group. In the C—O—H bond system, the electrons are shifted from H, facilitating loss of the H as a proton. (Section 16.10)

(**b**) To determine the extent of ionization, we first set up the ionization equilibrium and equilibrium-constant expression. Using HPv as the symbol for the acid, we have

$$HPv \rightleftharpoons H^+ + Pv^-$$

$$K_a = \frac{[H^+][Pv^-]}{[HPv]} = 3.2 \times 10^{-3}$$

Let $[Pv^-] = x$. Then the concentration of undissociated acid is $2 \times 10^{-4} - x$. The concentration of $[H^+]$ is fixed at $4.0 \times 10^{-8}\,M$ (the antilog of the pH value). Substituting, we obtain

$$3.2 \times 10^{-3} = \frac{(4.0 \times 10^{-8})(x)}{(2 \times 10^{-4} - x)}$$

Solving for x, we obtain

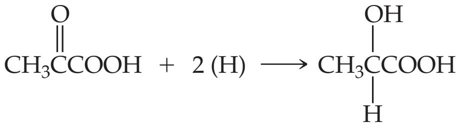
$$x = [Pv^-] = 2 \times 10^{-4}\,M$$

This is the initial concentration of acid, which means that essentially all the acid has dissociated. We might have expected this result because the acid is quite dilute and the acid-dissociation constant is fairly high.

(**c**) Pyruvic acid should be quite soluble in water because it has polar functional groups and a small hydrocarbon component. We would predict it would be soluble in polar organic solvents, especially ones that contain oxygen. In fact, pyruvic acid dissolves in water, ethanol, and diethyl ether.

(**d**) The methyl group carbon has sp^3 hybridization. The carbon of the carbonyl group has sp^2 hybridization because of the double bond to oxygen. Similarly, the carboxylic acid carbon is sp^2 hybridized.

(**e**) The balanced chemical equation for this reaction is



$$CH_3\overset{\overset{\displaystyle O}{\|}}{C}COOH + 2\,(H) \longrightarrow CH_3\underset{\underset{\displaystyle H}{|}}{\overset{\overset{\displaystyle OH}{|}}{C}}COOH$$

Essentially, the ketonic functional group has been reduced to an alcohol.

STRATEGIES FOR SUCCESS What Now?

If you are reading this box, you have made it to the end of our text. We congratulate you on the tenacity and dedication that you have exhibited to make it this far!

As an epilogue, we offer the ultimate study strategy in the form of a question: What do you plan to do with the knowledge of chemistry that you have gained thus far in your studies? Many of you will enroll in additional courses in chemistry as part of your required curriculum. For others, this will be the last formal course in chemistry that you will take. Regardless of the career path you plan to take—whether it is chemistry, one of the biomedical fields, engineering, the liberal arts, or another field—we hope that this text has increased your appreciation of the chemistry in the world around you. As you will observe, chemistry is everywhere, from food and pharmaceuticals to solar cells and sports equipment.

We have also tried to give you a sense that chemistry is a dynamic, continuously changing science. Research chemists synthesize new compounds, develop new reactions, uncover chemical properties that were previously unknown, find new applications for known compounds, and refine theories. The understanding of biological systems in terms of the underlying chemistry has become increasingly important as new levels of complexity are uncovered. Solving the global challenges of sustainable energy and clean water requires the work of many chemists. We encourage you to participate in the fascinating world of chemical research by enrolling in an undergraduate research program. Given all the answers that chemists seem to have, you may be surprised at the large number of questions that they still find to ask.

Finally, we hope you have enjoyed using this textbook. We certainly enjoyed sharing our experiences and perspectives on the fascinating world of chemistry with you. We truly believe it to be the central science, one that benefits all who learn about it and from it.

Chapter Summary and Key Terms

GENERAL CHARACTERISTICS OF ORGANIC COMPOUNDS (INTRODUCTION AND SECTION 24.1) This chapter introduces **organic chemistry**, which is the study of compounds containing carbon–hydrogen bonds, and **biochemistry**, which is the study of the chemistry of living organisms. $C{-}C$ single bonds and $C{-}H$ bonds tend to have low reactivity. Those bonds that have a high-electron density (such as multiple bonds or bonds with an atom of high electronegativity) tend to be the sites of reactivity in an organic compound. These sites of reactivity are called **functional groups**.

INTRODUCTION TO HYDROCARBONS (SECTION 24.2) The simplest types of organic compounds are hydrocarbons, those composed of only carbon and hydrogen. There are four major kinds of hydrocarbons: alkanes, alkenes, alkynes, and aromatic hydrocarbons. **Alkanes** are composed of only $C{-}H$ and $C{-}C$ single bonds. **Alkenes** contain one or more carbon–carbon double bonds. **Alkynes** contain one or more carbon–carbon triple bonds. **Aromatic hydrocarbons** contain cyclic arrangements of carbon atoms bonded through both σ and delocalized π bonds. Alkanes are saturated hydrocarbons; the others are unsaturated.

Alkanes may form straight-chain, branched-chain, and cyclic arrangements. Isomers are substances that possess the same molecular formula but differ in the arrangements of atoms. In **structural isomers**, the bonding arrangements of the atoms differ. Different isomers are given different systematic names. The naming of hydrocarbons is based on the longest continuous chain of carbon atoms in the structure. The locations of **alkyl groups**, which branch off the chain, are specified by numbering along the carbon chain.

Alkanes with ring structures are called **cycloalkanes**. Alkanes are relatively unreactive. They do, however, undergo combustion in air, and their chief use is as a source of heat produced by combustion reactions.

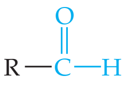
ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS (SECTION 24.3) The names of alkenes and alkynes are based on the longest continuous chain of carbon atoms that contains the multiple bond, and the location of the multiple bond is specified by a numerical prefix. Alkenes exhibit not only structural isomerism but geometric (cis–trans) isomerism as well. In **geometric isomers**, the bonds are the same, but the molecules have different geometries. Geometric isomerism is possible in alkenes because rotation about the $C{=}C$ double bond is restricted.

Alkenes and alkynes readily undergo **addition reactions** to the carbon–carbon multiple bonds. Addition reactions are difficult to carry out with aromatic hydrocarbons, but **substitution reactions** are easily accomplished in the presence of catalysts.

ORGANIC FUNCTIONAL GROUPS (SECTION 24.4) The chemistry of organic compounds is dominated by the nature of their functional groups. The functional groups we have considered are

$R{-}O{-}H$

Alcohol



$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}H$

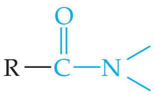
Aldehyde

$\rangle C{=}C\langle$

Alkene

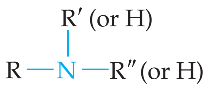
${-}C{\equiv}C{-}$

Alkyne



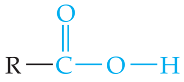
$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}N\langle$

Amide



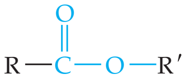
$R{-}\overset{\displaystyle R'\,(\text{or H})}{\overset{|}{N}}{-}R''\,(\text{or H})$

Amine



$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}O{-}H$

Carboxylic acid

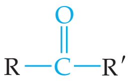


$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}O{-}R'$

Ester

$R{-}O{-}R'$

Ether



$R{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}R'$

Ketone

R, R′ and R″ represent hydrocarbon groups—for example, methyl (CH_3) or phenyl (C_6H_5).

Alcohols are hydrocarbon derivatives containing one or more OH groups. **Ethers** are formed by a condensation reaction of two molecules of alcohol. Several functional groups contain the **carbonyl ($C{=}O$) group**, including **aldehydes**, **ketones**, **carboxylic acids**, **esters**, and **amides**. Aldehydes and ketones can be produced by the oxidation of certain alcohols. Further oxidation of the aldehydes produces carboxylic acids. Carboxylic acids can form esters by a condensation reaction with alcohols, or they can form amides by a condensation reaction with amines. Esters undergo **hydrolysis** (**saponification**) in the presence of strong bases.

CHIRALITY IN ORGANIC CHEMISTRY (SECTION 24.5) Molecules that possess nonsuperimposable mirror images are said to be **chiral**. The two nonsuperimposable forms of a chiral molecule are called *enantiomers*. In carbon compounds, a chiral center is created when all four groups bonded to a central carbon atom are different. Many of the molecules occurring in living systems, such as the amino acids, are chiral and exist in nature in only one enantiomeric form. Many drugs of importance in human medicine are chiral, and the enantiomers may produce very different biochemical effects.

PROTEINS (SECTION 24.6) Many of the molecules that are essential for life are large natural polymers that are constructed from smaller molecules called monomers. Three of these **biopolymers** are considered in this chapter: proteins, polysaccharides (carbohydrates), and nucleic acids.

Proteins are polymers of **amino acids**. They are the major structural materials in animal systems. All naturally occurring proteins are formed from 22 amino acids, although only 20 are common. The amino acids are linked by **peptide bonds**. A **polypeptide** is a polymer formed by linking many amino acids by peptide bonds.

Amino acids are chiral substances. Usually, only one of the enantiomers is found to be biologically active. Protein structure is determined by the sequence of amino acids in the chain (its **primary structure**), the intramolecular interactions within the chain (its **secondary structure**), and the overall shape of the complete molecule (its **tertiary structure**). Two important secondary structures are the **α-helix** and the **β-sheet**. The process by which a protein assumes its biologically active tertiary structure is called **folding**. Sometimes several proteins aggregate together to form a **quaternary structure**.

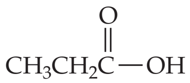
CARBOHYDRATES AND LIPIDS (SECTIONS 24.7 AND 24.8) **Carbohydrates**, which are polyhydroxy aldehydes and ketones, are the major structural constituents of plants and are a source of energy in both plants and animals. **Glucose** is the most common **monosaccharide**, or simple sugar. Two monosaccharides can be linked together by means of a condensation reaction to form a **disaccharide**. **Polysaccharides** are complex carbohydrates made up of many monosaccharide units joined together. The three most important polysaccharides are **starch** and **cellulose**, both of which are found in plants, and **glycogen**, which is found in mammals.

Lipids are compounds formed from condensation reactions between glycerol and fatty acids. They include fats and **phospholipids**. Fatty acids can be saturated, unsaturated, cis, or trans, depending on their chemical formulas and structures.

NUCLEIC ACIDS (SECTION 24.9) **Nucleic acids** are biopolymers that carry the genetic information necessary for cell reproduction; they also control cell development through control of protein synthesis. The building blocks of these biopolymers are **nucleotides**. There are two types of nucleic acids, **ribonucleic acid (RNA)** and **deoxyribonucleic acid (DNA)**. These substances consist of a polymeric backbone of alternating phosphate and ribose or deoxyribose sugar groups with organic bases attached to the sugar molecules. The DNA polymer is a double-stranded helix (**double helix**) held together by hydrogen bonding between matching organic bases situated across from one another on the two strands. The hydrogen bonding between specific base pairs is the key to gene replication and protein synthesis.

Exam Prep

EP 24.1 Predict the bond angle of the O—C—O bond in the following molecule:



$$\mathrm{CH_3CH_2}\overset{\overset{\displaystyle \mathrm{O}}{\|}}{\mathrm{C}}\mathrm{-OH}$$

(**a**) exactly 90°
(**b**) slightly greater than 90°
(**c**) exactly 120°
(**d**) slightly less than 120°
(**e**) slightly greater than 120°

EP 24.2 How many distinct locations are there for a double bond in a six-carbon linear chain? (**a**) 1 (**b**) 2 (**c**) 3 (**d**) 4 (**e**) 5

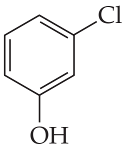
EP 24.3 Which of the following compounds does *not* exist? (**a**) 1,3,5,7-octatetraene (**b**) *cis*-2-butane (**c**) *trans*-3-hexene (**d**) 1-propene (**e**) *cis*-4-decene

EP 24.4 How many hydrogen atoms are in 3-ethyl-2,3-dimethylpentane? (**a**) 5 (**b**) 9 (**c**) 12 (**d**) 18 (**e**) 20

EP 24.5 What is the relationship between 2,3-dimethylpentane and 3-methylhexane?

(**a**) They are geometric isomers.
(**b**) They are structural isomers.
(**c**) They are optical isomers (enantiomers).
(**d**) They are *not* isomers.

EP 24.6 The following compound is a(n) ______ with a molecular formula of ______.



(**a**) aromatic hydrocarbon, C_6ClOH
(**b**) aromatic hydrocarbon, C_6H_4ClOH
(**c**) aromatic hydrocarbon, C_6H_8ClOH
(**d**) alkene, C_6H_4ClOH
(**e**) alkene, C_6H_8ClOH

EP 24.7 Which of the following molecules is capable of geometric isomerism?

(**i**) 1-butene
(**ii**) 2-butene

(**a**) only i (**b**) only ii (**c**) both i and ii (**d**) neither i nor ii

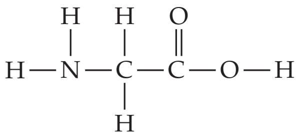
EP 24.8 What product is formed from the hydrogenation of 2-methylpropene? (**a**) propane (**b**) butane (**c**) 2-methylbutane (**d**) 2-methylpropane (**e**) 2-methylpropyne

EP 24.9 Which types of organic compounds readily undergo addition reactions?

(**i**) alkenes
(**ii**) alkynes
(**iii**) aromatic hydrocarbons

(**a**) only i (**b**) only iii (**c**) both i and ii (**d**) both i and iii (**e**) All three readily undergo addition reactions.

EP 24.10 The amino acid glycine contains which functional groups?



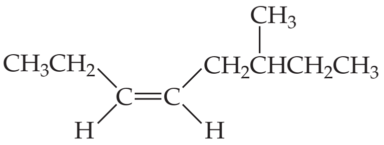
$$\begin{array}{ccccccccccc} & & \mathrm{H} & & \mathrm{H} & & \mathrm{O} & & & & \\ & & | & & | & & \| & & & & \\ \mathrm{H} & - & \mathrm{N} & - & \mathrm{C} & - & \mathrm{C} & - & \mathrm{O} & - & \mathrm{H} \\ & & & & | & & & & & & \\ & & & & \mathrm{H} & & & & & & \end{array}$$

(**a**) amine, alcohol
(**b**) amide, alcohol
(**c**) amine, carboxylic acid
(**d**) amide, carboxylic acid
(**e**) amine, alkene, alcohol

EP 24.11 A condensation reaction between ______ and ______ results in the formation of an ester.

(**a**) an aldehyde, alcohol
(**b**) an alcohol, alcohol
(**c**) a carboxylic acid, alcohol
(**d**) a carboxylic acid, amine
(**e**) a carboxylic acid, carboxylic acid

EP 24.12 How many chiral carbons are in the following molecule?



(**a**) 1 (**b**) 2 (**c**) 3 (**d**) 5 (**e**) 8

EP 24.13 How many nitrogen atoms are in the tripeptide Arg-Asp-Gly? (**a**) 3 (**b**) 4 (**c**) 5 (**d**) 6 (**e**) 7

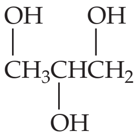
EP 24.14 Which statement describing the structure and composition of different amino acids is *false*?

(**a**) The carboxylic acid and amine groups are always bonded to the α-carbon.
(**b**) All amino acids can form zwitterions.
(**c**) The hybridization at the α-carbon is always sp^3.
(**d**) The α-carbon is usually, but not always, a chiral center.
(**e**) The —R group contains only carbon and hydrogen, but the number of atoms in this group differs from one amino acid to another.

EP 24.15 If you heat a protein to a sufficiently high temperature to break intramolecular hydrogen bonds, but not covalent bonds, will the α-helical and/or β-sheet structure be retained?

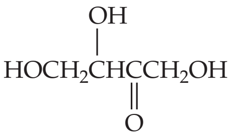
(**a**) The α-helical structure will remain, but not the β-sheet structure.
(**b**) The β-sheet structure will remain, but not the α-helical structure.
(**c**) Both the α-helical structure and the β-sheet structure will be retained.
(**d**) Neither the α-helical structure nor the β-sheet structure will be retained.

EP 24.16 Which of the following molecules is a carbohydrate?



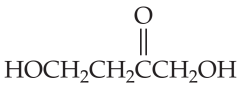
$\overset{OH}{\overset{|}{C}}H_3\underset{\underset{OH}{|}}{C}H\overset{OH}{\overset{|}{C}}H_2$

(i)



$HOCH_2\overset{OH}{\overset{|}{C}}H\underset{\underset{O}{\|}}{C}CH_2OH$

(ii)

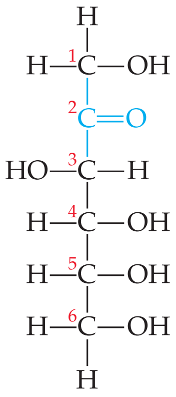


$HOCH_2CH_2\overset{O}{\overset{\|}{C}}CH_2OH$

(iii)

(**a**) only i (**b**) only ii (**c**) only iii (**d**) both i and ii (**e**) both ii and iii

EP 24.17 How many chiral carbon atoms are there in the open-chain form of fructose?



$$\begin{array}{c} H \\ | \\ H-{}^{1}C-OH \\ | \\ {}^{2}C=O \\ | \\ HO-{}^{3}C-H \\ | \\ H-{}^{4}C-OH \\ | \\ H-{}^{5}C-OH \\ | \\ H-{}^{6}C-OH \\ | \\ H \end{array}$$

Fructose

(**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4

EP 24.18 What is the relationship between the monosaccharides glucose and galactose (see Figure 24.21 for drawings of the ring forms of these two molecules)?

(**a**) The two molecules are structural isomers.

(**b**) The two molecules are geometric isomers.

(**c**) The two molecules are optical isomers.

(**d**) The two molecules are *not* isomers.

EP 24.19 Disaccharides, peptides, fats, and polynucleotides are all formed by what type of reaction? (**a**) addition (**b**) oxidation (**c**) condensation (**d**) hydrogenation (**e**) carbonylation

EP 24.20 Which of the following statements is or are *true*?

(**i**) Fats are lipids derived from glycerol and fatty acids.

(**ii**) Trans fats are saturated fats.

(**iii**) Phospholipids are a key component of cell membranes because they form a bilayer containing a polar and non-polar end.

(**a**) only i (**b**) both i and ii (**c**) both i and iii (**d**) both ii and iii (**e**) All three statements are true.

EP 24.21 Which class of biomolecules will be the least soluble in water? (**a**) proteins (**b**) amino acids (**c**) carbohydrates (**d**) lipids (**e**) nucleic acids

EP 24.22 In the double-helix structure of DNA, which base forms hydrogen bonds with thymine? (**a**) adenine (**b**) guanine (**c**) cytosine (**d**) uracil

EP 24.23 Imagine a single DNA strand with the following base sequence: 5′–GACCTTA–3′. What is the base sequence of the complementary strand?

(**a**) 3′–GACCTTA–5′ (**b**) 3′–AGTTCCA–5′ (**c**) 3′–TCAAGGC–5′ (**d**) 3′–CTGGAAT–5′

EP 24.24 Which of the following comparisons of DNAs and RNAs is *false*?

(**a**) DNAs and RNAs contain different sugar molecules in their backbone.

(**b**) DNAs and RNAs are built from the same nitrogen-containing bases.

(**c**) DNA molecules are normally much larger than RNA molecules.

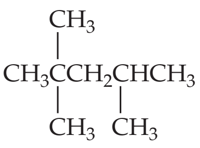
(**d**) DNAs are typically found in the cell nucleus, while RNAs are found outside the cell nucleus.

(**e**) DNAs and RNAs are both biopolymers.

Exercises

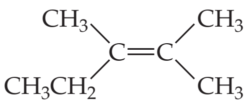
Visualizing Concepts

24.1 Give the systematic name for each of these hydrocarbons. [Sections 24.2, 24.3]

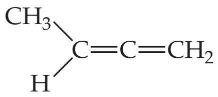


$CH_3\overset{CH_3}{\overset{|}{\underset{\underset{CH_3}{|}}{C}}}CH_2\underset{\underset{CH_3}{|}}{C}HCH_3$

(a)



(b)



(c)

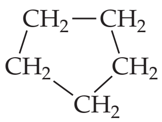
$CH_3CH_2C\equiv CH$

(d)

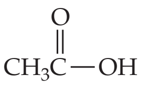
24.2 Which of these molecules is unsaturated? [Section 24.3]

$CH_3CH_2CH_2CH_3$

(a)



(b)



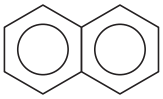
$CH_3\overset{O}{\overset{\|}{C}}-OH$

(c)

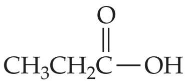
$CH_3CH=CHCH_3$

(d)

24.3 (**a**) Which of these molecules most readily undergoes an addition reaction? (**b**) Which of these molecules is aromatic? (**c**) Which of these molecules most readily undergoes a substitution reaction? [Section 24.3]

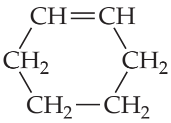


(i)

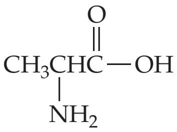


$CH_3CH_2\overset{O}{\overset{\|}{C}}{-}OH$

(ii)



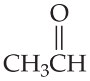
(iii)



$CH_3\underset{NH_2}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}{-}OH$

(iv)

24.4 (**a**) Which of these compounds would you expect to have the highest boiling point? (**b**) Which of these compounds is the most oxidized? (**c**) Which of these compounds, if any, is an ether? (**d**) Which of these compounds, if any, is an ester? (**e**) Which of these compounds, if any, is a ketone? [Section 24.4]



$CH_3\overset{O}{\overset{\|}{C}}H$

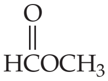
(i)

CH_3CH_2OH

(ii)

$CH_3C\equiv CH$

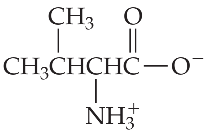
(iii)



$H\overset{O}{\overset{\|}{C}}OCH_3$

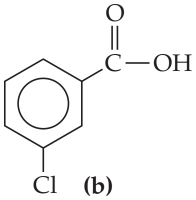
(iv)

24.5 For each of the following compounds, state its systematic name, its functional group(s), and whether or not it is chiral. [Sections 24.2, 24.4]



$CH_3\overset{CH_3}{\overset{|}{C}}H\underset{NH_3^+}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}{-}O^-$

(a)



(b)

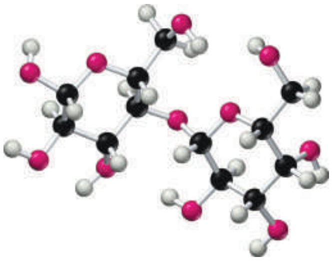
$CH_3CH_2CH=CHCH_3$

(c)

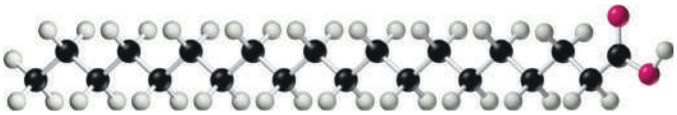
$CH_3CH_2CH_3$

(d)

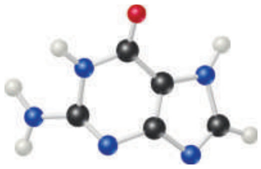
24.6 From examination of the molecular models i–v, choose the substance that (**a**) can be hydrolyzed to form a solution containing glucose, (**b**) is capable of forming a zwitterion, (**c**) is one of the four bases present in DNA, (**d**) reacts with an acid to form an ester, (**e**) is a lipid. [Sections 24.6–24.9]



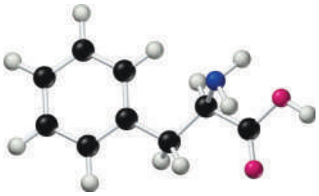
(i)



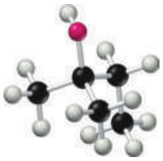
(ii)



(iii)



(iv)



(v)

Introduction to Organic Compounds; Hydrocarbons (Sections 24.1 and 24.2)

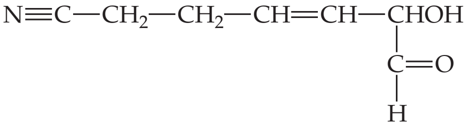
24.7 Indicate whether each statement is *true* or *false*. (**a**) Butane contains carbons that are sp^2 hybridized. (**b**) Cyclohexane is another name for benzene. (**c**) The isopropyl group contains three sp^3-hybridized carbons. (**d**) Olefin is another name for alkyne.

24.8 Indicate whether each statement is *true* or *false*. (**a**) Pentane has a higher molar mass than hexane. (**b**) The longer the linear alkyl chain for straight-chain hydrocarbons, the higher the boiling point. (**c**) The local geometry around the alkyne group is linear. (**d**) Propane has two structural isomers.

24.9 Predict the ideal values for the bond angles about each carbon atom in the following molecule. Indicate the hybridization of orbitals for each carbon.

$$CH_3CCCH_2COOH$$

24.10 Identify the carbon atom(s) in the structure shown that has (have) each of the following hybridizations: (**a**) sp^3, (**b**) sp, (**c**) sp^2.



$$N\equiv C-CH_2-CH_2-CH=CH-\underset{\underset{\underset{H}{|}}{C=O}}{\underset{|}{C}}HOH$$

24.11 For each of the following hydrocarbons, state how many carbon atoms are in each molecule:

(**a**) methane

(**b**) decane

(**c**) 2-methylhexane

(**d**) neopentane

(**e**) acetylene

24.12 *True* or *false*: The weaker a single bond in a molecule, the greater the chance it will be the site of a reaction (compared to stronger single bonds in the molecule).

24.13 Indicate whether each statement is *true* or *false*. (**a**) Alkanes do not contain any carbon–carbon multiple bonds. (**b**) Cyclobutane contains a four-membered ring. (**c**) Alkenes contain carbon–carbon triple bonds. (**d**) Alkynes contain carbon–carbon double bonds. (**e**) Pentane is a saturated hydrocarbon, but 1-pentene is an unsaturated hydrocarbon. (**f**) Cyclohexane is an aromatic hydrocarbon. (**g**) The methyl group contains one less hydrogen atom than methane.

24.14 What structural features help us identify a compound as (**a**) an alkane, (**b**) a cycloalkane, (**c**) an alkene, (**d**) an alkyne, (**e**) a saturated hydrocarbon, (**f**) an aromatic hydrocarbon?

24.15 Give the name or condensed structural formula, as appropriate:

(**a**) $$\begin{array}{l} CH_3CHCH_3 \\ \quad | \\ \quad CHCH_2CH_2CH_2CH_3 \\ \quad | \\ \quad CH_3 \end{array}$$

(**b**) 2,2-dimethylpentane

(**c**) 4-ethyl-1,1-dimethylcyclohexane

(**d**) $(CH_3)_2CHCH_2CH_2C(CH_3)_3$

(**e**) $CH_3CH_2CH(C_2H_5)CH_2CH_2CH_2CH_3$

24.16 Give the name or condensed structural formula, as appropriate:

(**a**) 3-phenylpentane

(**b**) 2,3-dimethylhexane

(**c**) 3,3-dimethyloctane

(**d**) $CH_3CH_2CH(CH_3)CH_2CH(CH_3)_2$

(**e**) 
Alkenes, Alkynes, and Aromatic Hydrocarbons (Section 24.3)

24.17 (**a**) Is C_4H_6 a saturated or unsaturated hydrocarbon?

(**b**) Are all alkynes unsaturated?

24.18 (**a**) Is the compound $CH_3CH{=}CH_2$ saturated or unsaturated? Explain. (**b**) What is wrong with the formula $CH_3CH_2CH{=}CH_3$?

24.19 Give the molecular formula of a hydrocarbon containing five carbon atoms that is (**a**) an alkane, (**b**) a cycloalkane, (**c**) an alkene, (**d**) an alkyne.

24.20 Give the molecular formula of a hydrocarbon containing six carbon atoms that is (**a**) a cyclic alkane, (**b**) a cyclic alkene, (**c**) a linear alkyne, (**d**) an aromatic hydrocarbon.

24.21 Enediynes are a class of compounds that include some antibiotic drugs. Draw the structure of an "enediyne" fragment that contains six carbons in a row.

24.22 Give the general formula for any cyclic alkene—that is, a cyclic hydrocarbon with one double bond.

24.23 Write the condensed structural formulas for two alkenes and one alkyne that all have the molecular formula C_6H_{10}.

24.24 Draw all the possible noncyclic structural isomers of C_5H_{10}. Name each compound.

24.25 Name or write the condensed structural formula for the following compounds:

(**a**) *trans*-2-pentene

(**b**) 2,5-dimethyl-4-octene

(**c**) 
(**d**) 
(**e**) $$\begin{array}{l} \qquad\qquad\quad CH_2CH_3 \\ \qquad\qquad\quad | \\ HC{\equiv}CCH_2CCH_3 \\ \qquad\qquad\quad | \\ \qquad\qquad\quad CH_3 \end{array}$$

24.26 Name or write the condensed structural formula for the following compounds:

(**a**) 4-methyl-2-pentene

(**b**) *cis*-2,5-dimethyl-3-hexene

(**c**) *ortho*-dimethylbenzene

(**d**) $HC{\equiv}CCH_2CH_3$

(**e**) *trans* – $CH_3CH{=}CHCH_2CH_2CH_2CH_3$

24.27 Indicate whether each statement is *true* or *false*. (**a**) Two geometric isomers of pentane are *n*-pentane and neopentane. (**b**) Alkenes can have cis and trans isomers around the carbon–carbon double bond. (**c**) Alkynes can have cis and trans isomers around the carbon–carbon triple bond.

24.28 Draw all structural and geometric isomers of butene and name them.

24.29 Indicate whether each of the following molecules is capable of geometrical isomerism. For those that are, draw the structures: (**a**) 1,1-dichloro-1-butene, (**b**) 2,4-dichloro-2-butene, (**c**) 1,4-dichlorobenzene, (**d**) 4,4-dimethyl-2-pentyne.

24.30 Draw the three distinct geometric isomers of 2,4-hexadiene.

24.31 (**a**) *True* or *false*: Alkenes undergo addition reactions, and aromatic hydrocarbons undergo substitution reactions. (**b**) Using condensed structural formulas, write the balanced equation for the reaction of 2-pentene with Br_2 and name the resulting compound. Is this an addition or a substitution reaction? (**c**) Write a balanced chemical equation for the reaction of Cl_2 with benzene to make *para*-dichlorobenzene in the presence of $FeCl_3$ as a catalyst. Is this an addition or a substitution reaction?

24.32 Using condensed structural formulas, write a balanced chemical equation for each of the following reactions: (**a**) hydrogenation of cyclohexene, (**b**) addition of H_2O to *trans*-2-pentene using H_2SO_4 as a catalyst (two products), (**c**) reaction of 2-chloropropane with benzene in the presence of $AlCl_3$.

24.33 (**a**) When cyclopropane is treated with HI, 1-iodopropane is formed. A similar type of reaction does not occur with cyclopentane or cyclohexane. Suggest an explanation for cyclopropane's reactivity. (**b**) Suggest a method of preparing ethylbenzene, starting with benzene and ethylene as the only organic reagents.

24.34 (**a**) One test for the presence of an alkene is to add a small amount of bromine, which is a red-brown liquid, and look for the disappearance of the red-brown color. This test does not work for detecting the presence of an aromatic hydrocarbon. Explain. (**b**) Write a series of reactions leading to *para*-bromoethylbenzene, beginning with benzene and using other reagents as needed. What isomeric side products might also be formed?

24.35 The rate law for addition of Br_2 to an alkene is first order in Br_2 and first order in the alkene. Does this information suggest that the mechanism of addition of Br_2 to an alkene proceeds in the same manner as for addition of HBr? Explain.

24.36 Describe the intermediate that is thought to form in the addition of a hydrogen halide to an alkene, using cyclohexene as the alkene in your description.

24.37 The molar heat of combustion of gaseous cyclopropane is -2089 kJ/mol; that for gaseous cyclopentane is -3317 kJ/mol. Calculate the heat of combustion per CH_2 group in the two cases, and account for the difference.

24.38 The heat of combustion of decahydronaphthalene ($C_{10}H_{18}$) is -6286 kJ/mol. The heat of combustion of naphthalene ($C_{10}H_8$) is -5157 kJ/mol. [In both cases, $CO_2(g)$ and $H_2O(l)$ are the products.] Using these data and data in Appendix C, calculate the heat of hydrogenation and the resonance energy of naphthalene.

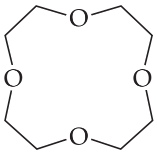
Functional Groups and Chirality (Sections 24.4 and 24.5)

24.39 (**a**) Which of the following compounds, if any, is an ether? (**b**) Which compound, if any, is an alcohol? (**c**) Which compound, if any, would produce a basic solution if dissolved in water? (Assume solubility is not a problem). (**d**) Which compound, if any, is a ketone? (**e**) Which compound, if any, is an aldehyde?

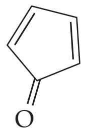
(i) H_3C-CH_2-OH

(ii)
$H_3C-\overset{H}{N}-CH_2CH=CH_2$

(ii)



(iv)

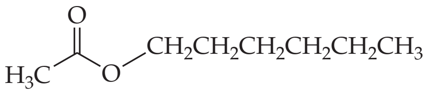


(v) $CH_3CH_2CH_2CH_2CHO$

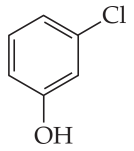
(vi) $CH_3C\equiv CCH_2COOH$

24.40 Identify the functional groups in each of the following compounds:

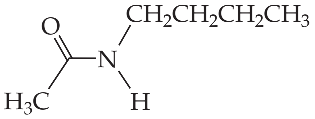
(**a**)



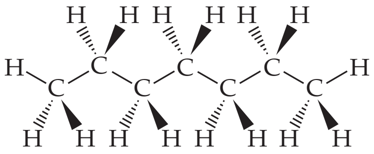
(**b**)



(**c**)

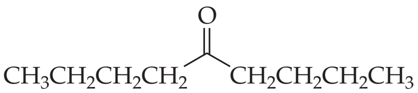


(**d**)



(**e**)

(**f**)



24.41 Draw the molecular structure for (**a**) an aldehyde that is an isomer of acetone, (**b**) an ether that is an isomer of 1-propanol.

24.42 (**a**) Give the empirical formula and structural formula for a cyclic ether containing four carbon atoms in the ring. (**b**) Write the structural formula for a straight-chain compound that is a structural isomer of your answer to part (a).

24.43 The IUPAC name for a carboxylic acid is based on the name of the hydrocarbon with the same number of carbon atoms. The ending *-oic* is appended, as in ethanoic acid, which is the IUPAC name for acetic acid. Draw the structure of the following acids: (**a**) methanoic acid, (**b**) pentanoic acid, (**c**) 2-chloro-3-methyldecanoic acid.

24.44 Aldehydes and ketones can be named in a systematic way by counting the number of carbon atoms (including the carbonyl carbon) that they contain. The name of the aldehyde or ketone is based on the hydrocarbon with the same number of carbon atoms. The ending *-al* for aldehyde or *-one* for ketone is added as appropriate. Draw the structural formulas for the following aldehydes or ketones: (**a**) propanal, (**b**) 2-pentanone, (**c**) 3-methyl-2-butanone, (**d**) 2-methylbutanal.

24.45 Draw the condensed structure of the compounds formed by condensation reactions between (**a**) benzoic acid and ethanol, (**b**) ethanoic acid and methylamine, (**c**) acetic acid and phenol. Name the compound in each case.

24.46 Draw the condensed structures of the compounds formed from (**a**) butanoic acid and methanol, (**b**) benzoic acid and 2-propanol, (**c**) propanoic acid and dimethylamine. Name the compound in each case.

24.47 Write a balanced chemical equation using condensed structural formulas for the saponification (base hydrolysis) of (**a**) methyl propionate, (**b**) phenyl acetate.

24.48 Write a balanced chemical equation using condensed structural formulas for (**a**) the formation of butyl propionate from the appropriate acid and alcohol, (**b**) the saponification (base hydrolysis) of methyl benzoate.

24.49 Pure acetic acid is a viscous liquid, with high melting and boiling points (16.7 °C and 118 °C) compared to compounds of similar molecular weight. Suggest an explanation.

24.50 *Acetic anhydride* is formed from two acetic acid molecules, in a condensation reaction that involves the removal of a molecule of water. Write the chemical equation for this process and show the structure of acetic anhydride.

24.51 Write the condensed structural formula for each of the following compounds: (**a**) 2-pentanol, (**b**) 1,2-propanediol, (**c**) ethyl acetate, (**d**) diphenyl ketone, (**e**) methyl ethyl ether.

24.52 Write the condensed structural formula for each of the following compounds: (**a**) 2-ethyl-1-hexanol, (**b**) methyl phenyl ketone, (**c**) *para*-bromobenzoic acid, (**d**) butyl ethyl ether, (**e**) *N,N*-dimethylbenzamide.

24.53 How many chiral carbons are in 2-bromo-2-chloro-3-methylpentane? (**a**) 0 (**b**) 1 (**c**) 2 (**d**) 3 (**e**) 4 or more

24.54 Is 3-chloro-3-methylhexane chiral?

Proteins (Section 24.6)

24.55 (**a**) Draw the chemical structure of a generic amino acid, using R for the side chain. (**b**) When amino acids react to form proteins, do they do so via substitution, addition, or condensation reactions? (**c**) Draw the bond that links amino acids together in proteins. What is this called?

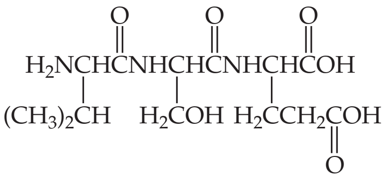
24.56 Indicate whether each statement is *true* or *false*. (**a**) Tryptophan is an aromatic amino acid. (**b**) Lysine is positively charged at pH 7. (**c**) Asparagine has two amide bonds. (**d**) Isoleucine and leucine are enantiomers. (**e**) Valine is probably more water-soluble than arginine.

24.57 Draw the two possible dipeptides formed by condensation reactions between histidine and aspartic acid.

24.58 Write a chemical equation for the formation of methionylglycine from the constituent amino acids.

24.59 (**a**) Draw the condensed structure of the tripeptide Gly-Gly-His. (**b**) How many different tripeptides can be made from the amino acids glycine and histidine? Give the abbreviations for each of these tripeptides, using the three-letter and one-letter codes for the amino acids.

24.60 (**a**) What amino acids would be obtained by hydrolysis of the following tripeptide?



$$H_2N\underset{(CH_3)_2CH}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}NH\underset{H_2COH}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}NH\underset{H_2CCH_2\underset{O}{\underset{\|}{C}}OH}{\underset{|}{C}}H\overset{O}{\overset{\|}{C}}OH$$

(**b**) How many different tripeptides can be made from glycine, serine, and glutamic acid? Give the abbreviation for each of these tripeptides, using the three-letter codes and one-letter codes for the amino acids.

24.61 Indicate whether each statement is *true* or *false*. (**a**) The sequence of amino acids in a protein, from the amine end to the acid end, is called the primary structure of the protein. (**b**) Alpha helix and beta sheet structures are examples of quaternary protein structure. (**c**) It is impossible for more than one protein to bind to another and make a higher-order structure.

24.62 Indicate whether each statement is *true* or *false*: (**a**) In the alpha helical structure of proteins, hydrogen bonding occurs between the side chains (R groups). (**b**) Dispersion forces, not hydrogen bonding, holds beta sheet structures together.

Carbohydrates and Lipids (Sections 24.7 and 24.8)

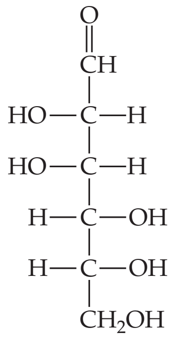
24.63 Indicate whether each statement is *true* or *false*: (**a**) Disaccharides are a type of carbohydrate. (**b**) Sucrose is a monosaccharide. (**c**) All carbohydrates have the formula $C_nH_{2m}O_m$.

24.64 (a) Are α-glucose and β-glucose enantiomers? (**b**) Show the condensation of two glucose molecules to form a disaccharide with an α linkage. (**c**) Repeat part (b) but with a β linkage.

24.65 (**a**) What is the empirical formula of cellulose? (**b**) What is the monomer that forms the basis of the cellulose polymer? (**c**) What bond connects the monomer units in cellulose: amide, acid, ether, ester, or alcohol?

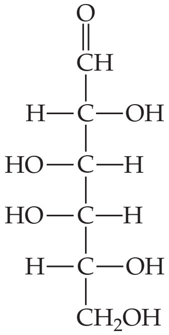
24.66 (**a**) What is the empirical formula of starch? (**b**) What is the monomer that forms the basis of the starch polymer? (**c**) What bond connects the monomer units in starch: amide, acid, ether, ester, or alcohol?

24.67 The structural formula for the open-chain form of D-mannose is



(**a**) Is this molecule a sugar? (**b**) How many chiral carbons are present in the molecule? (**c**) Draw the structure of the six-member-ring form of this molecule.

24.68 The structural formula for the open-chain form of galactose is



(**a**) Is this molecule a sugar? (**b**) How many chiral carbons are present in the molecule? (**c**) Draw the structure of the six-member-ring form of this molecule.

24.69 Indicate whether each statement is *true* or *false*: (**a**) Fat molecules contain amide bonds. (**b**) Phospholipids can be zwitterions. (**c**) Phospholipids form bilayers in water in order to have their long hydrophobic tails interact favorably with each other, leaving their polar heads to the aqueous environment.

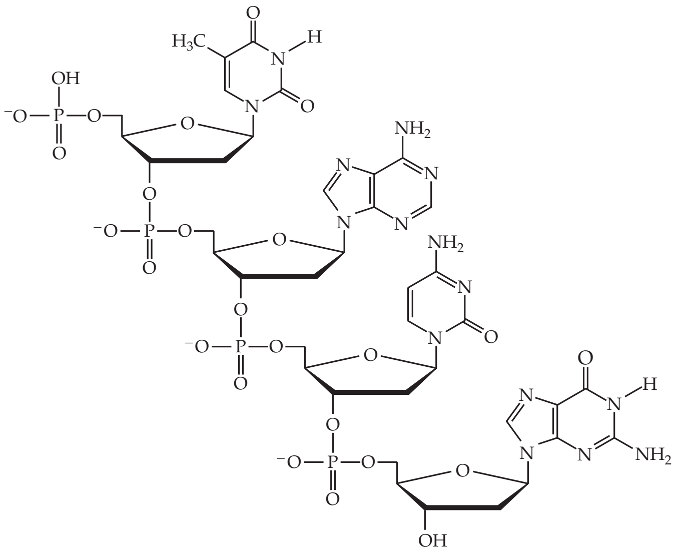
24.70 Indicate whether each statement is *true* or *false*: (**a**) If you use data from Table 8.3 on bond enthalpies, you can show that the more C—H bonds a molecule has compared to C—O and O—H bonds, the more energy it can store. (**b**) Trans fats are saturated. (**c**) Fatty acids are long-chain carboxylic acids. (**d**) Monounsaturated fatty acids have one C—C single bond in the chain, while the rest are double or triple bonds.

Nucleic Acids (Section 24.9)

24.71 Adenine and guanine are members of a class of molecules known as *purines*; they have two rings in their structure. Thymine and cytosine, on the other hand, are *pyrimidines* and have only one ring in their structure. Predict which have larger dispersion forces in aqueous solution, the purines or the pyrimidines.

24.72 A nucleoside consists of an organic base of the kind shown in Section 24.9, bound to ribose or deoxyribose. Draw the structure for deoxyguanosine, formed from guanine and deoxyribose.

24.73 What is the DNA sequence for the molecule shown here?



24.74 You are working in a biotechnology lab and are analyzing DNA. You obtain a sample of a short dodecamer of DNA that contains 12 base pairs. (**a**) What must the ratio of adenine to thymine be in your sample? (**b**) What must the ratio of cytosine to guanine be in your sample? (**c**) Assume the counterions present in your DNA solution are sodium ions. How many sodium ions must there be per dodecamer? Assume the 5′ end phosphates each bear a −1 charge.

24.75 Imagine a single DNA strand containing a section with the following base sequence: 5′-GCATTGGC-3′. What is the base sequence of the complementary strand?

24.76 Which statement best explains the chemical differences between DNA and RNA? (**a**) DNA has two different sugars in its sugar–phosphate backbone, but RNA only has one. (**b**) Thymine is one of the DNA bases, whereas RNA's corresponding base is thymine minus a methyl group. (**c**) The RNA sugar–phosphate backbone contains fewer oxygen atoms than DNA's backbone. (**d**) DNA forms double helices but RNA cannot.

Additional Exercises

24.77 Draw the condensed structural formulas for two different molecules with the formula C_3H_4O.

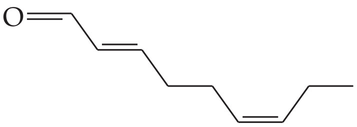
24.78 How many structural isomers are there for a five-member straight carbon chain with one double bond? For a six-member straight carbon chain with two double bonds?

24.79 (**a**) Draw the condensed structural formulas for the cis and trans isomers of 2-pentene. (**b**) Can cyclopentene exhibit cis–trans isomerism? Explain. (**c**) Does 1-pentyne have enantiomers? Explain.

24.80 If a molecule is an "ene-one," what functional groups must it have?

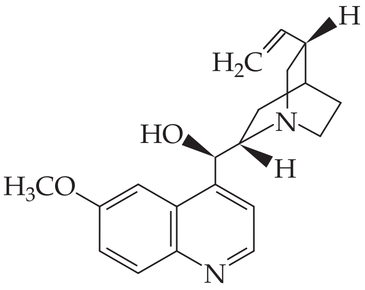
24.81 Identify each of the functional groups in these molecules:

(a)



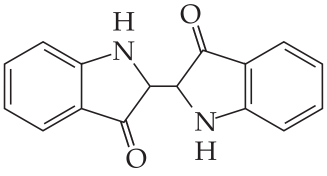
(Responsible for the odor of cucumbers)

(b)



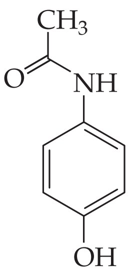
(Quinine — an antimalarial drug)

(c)



(Indigo — a blue dye)

(d)



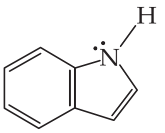
(Acetaminophen — aka Tylenol)

24.82 For the molecules shown in 24.81, (**a**) Which one(s) of them, if any, would produce a basic solution if dissolved in water? (**b**) Which one(s) of them, if any, would produce an acidic solution if dissolved in water? (**c**) Which of them is the most water-soluble?

24.83 Write a condensed structural formula for each of the following: (**a**) an acid with the formula $C_4H_8O_2$, (**b**) a cyclic ketone with the formula C_5H_8O, (**c**) a dihydroxy compound with the formula $C_3H_8O_2$, (**d**) a cyclic ester with the formula $C_5H_8O_2$.

24.84 Draw each molecule given its name and the following information. (**a**) Nitroglycerin, also known as 1,2,3-trinitroxypropane, the active ingredient in dynamite and a medication administered to people having a heart attack, (*Hint:* The nitroxy group is the conjugate base of nitric acid.) (**b**) Putrescine, also known as 1,4-diaminobutane, the compound responsible for the odor of putrefying fish, (**c**) Cyclohexanone, the precursor to Nylon, (**d**) 1,1,2,2-tetrafluoroethene, the precursor to Teflon, (**e**) Oleic acid, also known as *cis*-9-octanedecenoic acid, a monounsaturated fatty acid found in many fats and oils. Draw the correct isomer.

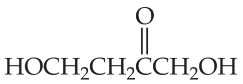
24.85 Indole smells terrible in high concentrations but has a pleasant floral-like odor when highly diluted. Its structure is



The molecule is planar, and the nitrogen is a very weak base, with $K_b = 2 \times 10^{-12}$. Explain how this information indicates that the indole molecule is aromatic.

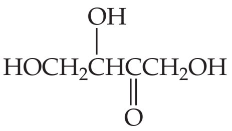
24.86 For each of the following molecules, identify its functional groups and how many chiral centers it contains.

(a)



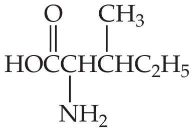
$\mathrm{HOCH_2CH_2\overset{\overset{\displaystyle O}{\|}}{C}CH_2OH}$

(b)



$\mathrm{HOCH_2\overset{\overset{\displaystyle OH}{|}}{C}H\underset{\underset{\displaystyle O}{\|}}{C}CH_2OH}$

(c)



$\mathrm{HO\overset{\overset{\displaystyle O}{\|}}{C}\underset{\underset{\displaystyle NH_2}{|}}{C}H\overset{\overset{\displaystyle CH_3}{|}}{C}HC_2H_5}$

24.87 Which of the following peptides have a net positive charge at pH 7? (**a**) Gly-Ser-Lys (**b**) Pro-Leu-Ile (**c**) Phe-Tyr-Asp

24.88 Glutathione is a tripeptide found in most living cells. Partial hydrolysis yields Cys-Gly and Glu-Cys. What structures are possible for glutathione?

24.89 Monosaccharides can be categorized in terms of the number of carbon atoms (pentoses have five carbons and hexoses have six carbons) and according to whether they contain an aldehyde (*aldo*- prefix, as in aldopentose) or ketone group (*keto*- prefix, as in ketopentose). Classify glucose and fructose in this way.

24.90 Can a DNA strand bind to a complementary RNA strand? Explain.

24.91 An organic compound is analyzed and found to contain 66.7% carbon, 11.2% hydrogen, and 22.1% oxygen by mass. The compound boils at 79.6 °C. At 100 °C and 0.970 atm, the vapor has a density of 2.28 g/L. The compound has a carbonyl group and cannot be oxidized to a carboxylic acid. Suggest a structure for the compound.

24.92 An unknown substance is found to contain only carbon and hydrogen. It is a liquid that boils at 49 °C at 1 atm pressure. Upon analysis, it is found to contain 85.7% carbon and 14.3% hydrogen by mass. At 100 °C and 735 torr, the vapor of this unknown has a density of 2.21 g/L. When it is dissolved in hexane solution and bromine water is added, no reaction occurs. What is the identity of the unknown compound?

Design an Experiment

Quaternary structures of proteins arise if two or more smaller polypeptides or proteins associate with each other to make a much larger protein structure. The association is due to the same hydrogen bonding, electrostatic, and dispersion forces we have seen before. Hemoglobin, the protein used to transport oxygen molecules in our blood, is an example of a protein that has quaternary structure. Hemoglobin is a tetramer; it is made of four smaller polypeptides, two “alphas” and two “betas.” (These names do not imply anything about the number of alpha helices or beta sheets in the individual polypeptides.) Design a set of experiments that would provide sound evidence that hemoglobin exists as a tetramer and not as one enormous polypeptide chain.

MATHEMATICAL OPERATIONS

APPENDIX A

A.1 | Exponential Notation

The numbers used in chemistry are often either extremely large or extremely small. Such numbers are conveniently expressed in the form

$$N \times 10^n$$

where N is a number between 1 and 10, and n is the exponent. Some examples of this *exponential notation*, which is also called *scientific notation*, follow.

1,200,000 is 1.2×10^6	(read "one point two multi ten to the sixth power")
0.000604 is 6.04×10^{-4}	(read "six point zero four times ten to the negative fourth power")

A positive exponent, as in the first example, tells us how many times a number must be multiplied by 10 to give the long form of the number:

$$\begin{aligned} 1.2 \times 10^6 &= 1.2 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \quad \text{(six tens)} \\ &= 1{,}200{,}000 \end{aligned}$$

It is also convenient to think of the *positive exponent* as the number of places the decimal point must be moved to the *left* to obtain a number greater than 1 and less than 10. For example, if we begin with 3450 and move the decimal point three places to the left, we end up with 3.45×10^3.

In a related fashion, a negative exponent tells us how many times we must divide a number by 10 to give the long form of the number.

$$6.04 \times 10^{-4} = \frac{6.04}{10 \times 10 \times 10 \times 10} = 0.000604$$

It is convenient to think of the *negative exponent* as the number of places the decimal point must be moved to the *right* to obtain a number greater than 1 but less than 10. For example, if we begin with 0.0048 and move the decimal point three places to the right, we end up with 4.8×10^{-3}.

In the system of exponential notation, with each shift of the decimal point one place to the right, the exponent *decreases* by 1:

$$4.8 \times 10^{-3} = 48 \times 10^{-4}$$

Similarly, with each shift of the decimal point one place to the left, the exponent *increases* by 1:

$$4.8 \times 10^{-3} = 0.48 \times 10^{-2}$$

Many scientific calculators have a key labeled EXP or EE, which is used to enter numbers in exponential notation. To enter the number 5.8×10^3 on such a calculator, the key sequence is

$$\boxed{5}\,\boxed{\cdot}\,\boxed{8}\,\boxed{\text{EXP}}\,(\text{or }\boxed{\text{EE}})\,\boxed{3}$$

On some calculators the display will show 5.8, then a space, followed by 03, the exponent. On other calculators, a small 10 is shown with an exponent 3.

To enter a negative exponent, use the key labeled +/−. For example, to enter the number 8.6×10^{-5}, the key sequence is

$$\boxed{8}\,\boxed{\cdot}\,\boxed{6}\,\boxed{\text{EXP}}\,\boxed{+/-}\,\boxed{5}$$

When entering a number in exponential notation, do not key in the 10 if you use the EXP or EE button.

In working with exponents, it is important to recall that $10^0 = 1$. The following rules are useful for carrying exponents through calculations.

1. **Addition and Subtraction** In order to add or subtract numbers expressed in exponential notation, the powers of 10 must be the same.

$$\begin{aligned}(5.22 \times 10^4) + (3.21 \times 10^2) &= (522 \times 10^2) + (3.21 \times 10^2)\\ &= 525 \times 10^2 \quad \text{(3 significant figures)}\\ &= 5.25 \times 10^4\\ (6.25 \times 10^{-2}) - (5.77 \times 10^{-3}) &= (6.25 \times 10^{-2}) - (0.577 \times 10^{-2})\\ &= 5.67 \times 10^{-2} \quad \text{(3 significant figures)}\end{aligned}$$

When you use a calculator to add or subtract, you need not be concerned with having numbers with the same exponents because the calculator automatically takes care of this matter.

2. **Multiplication and Division** When numbers expressed in exponential notation are multiplied, the exponents are added; when numbers expressed in exponential notation are divided, the exponent of the denominator is subtracted from the exponent of the numerator.

$$\begin{aligned}(5.4 \times 10^2)(2.1 \times 10^3) &= (5.4)(2.1) \times 10^{2+3}\\ &= 11 \times 10^5\\ &= 1.1 \times 10^6\\ (1.2 \times 10^5)(3.22 \times 10^{-3}) &= (1.2)(3.22) \times 10^{5+(-3)} = 3.9 \times 10^2\\ \frac{3.2 \times 10^5}{6.5 \times 10^2} &= \frac{3.2}{6.5} \times 10^{5-2} = 0.49 \times 10^3 = 4.9 \times 10^2\\ \frac{5.7 \times 10^7}{8.5 \times 10^{-2}} &= \frac{5.7}{8.5} \times 10^{7-(-2)} = 0.67 \times 10^9 = 6.7 \times 10^8\end{aligned}$$

3. **Powers and Roots** When numbers expressed in exponential notation are raised to a power, the exponents are multiplied by the power. When the roots of numbers expressed in exponential notation are taken, the exponents are divided by the root.

$$\begin{aligned}(1.2 \times 10^5)^3 &= (1.2)^3 \times 10^{5\times3}\\ &= 1.7 \times 10^{15}\\ \sqrt[3]{2.5 \times 10^6} &= \sqrt[3]{2.5} \times 10^{6/3}\\ &= 1.3 \times 10^2\end{aligned}$$

Scientific calculators usually have keys labeled x^2 and $\sqrt{x}$ for squaring and taking the square root of a number, respectively. To take higher powers or roots, many calculators have y^x and $\sqrt[x]{y}$ (or INV y^x) keys. For example, to perform the operation $\sqrt[3]{7.5 \times 10^{-4}}$ on such a calculator, you would key in 7.5×10^{-4}, press the $\sqrt[x]{y}$ key (or the INV and then the y^x keys), enter the root, 3, and finally press =. The result is 9.1×10^{-2}.

Sample Exercise 1

Using Exponential Notation

Perform each of the following operations, using your calculator where possible:

(a) Write the number 0.0054 in standard exponential notation. **(b)** $(5.0 \times 10^{-2}) + (4.7 \times 10^{-3})$ **(c)** $(5.98 \times 10^{12})(2.77 \times 10^{-5})$ **(d)** $\sqrt[4]{1.75 \times 10^{-12}}$

SOLUTION

(a) Because we move the decimal point three places to the right to convert 0.0054 to 5.4, the exponent is −3:

$$5.4 \times 10^{-3}$$

Scientific calculators are generally able to convert numbers to exponential notation using one or two keystrokes; frequently "SCI" for "scientific notation" will convert a number into exponential notation. Consult your instruction manual to see how this operation is accomplished on your calculator.

(**b**) To add these numbers longhand, we must convert them to the same exponent.

$$(5.0 \times 10^{-2}) + (0.47 \times 10^{-2}) = (5.0 + 0.47) \times 10^{-2} = 5.5 \times 10^{-2}$$

(**c**) Performing this operation longhand, we have

$$(5.98 \times 2.77) \times 10^{12-5} = 16.6 \times 10^{7} = 1.66 \times 10^{8}$$

(**d**) To perform this operation on a calculator, we enter the number, press the $\sqrt[x]{y}$ key (or the INV and y^x keys), enter 4, and press the = key. The result is 1.15×10^{-3}.

Practice Exercise

Perform the following operations:

(**a**) Write 67,000 in exponential notation, showing two significant figures.

(**b**) $(3.378 \times 10^{-3}) - (4.97 \times 10^{-5})$

(**c**) $(1.84 \times 10^{15})(7.45 \times 10^{-2})$

(**d**) $(6.67 \times 10^{-8})^3$

A.2 | Logarithms

Common Logarithms

The common, or base-10, logarithm (abbreviated log) of any number is the power to which 10 must be raised to equal the number. For example, the common logarithm of 1000 (written log 1000) is 3 because raising 10 to the third power gives 1000.

$$10^3 = 1000, \text{ therefore, } \log 1000 = 3$$

Further examples are

$$\log 10^5 = 5$$
$$\log 1 = 0 \quad \text{Remember that } 10^0 = 1$$
$$\log 10^{-2} = -2$$

In these examples the common logarithm can be obtained by inspection. However, it is not possible to obtain the logarithm of a number such as 31.25 by inspection. The logarithm of 31.25 is the number x that satisfies the following relationship:

$$10^x = 31.25$$

Most electronic calculators have a key labeled LOG that can be used to obtain logarithms. For example, on many calculators we obtain the value of log 31.25 by entering 31.25 and pressing the LOG key. We obtain the following result:

$$\log 31.25 = 1.4949$$

Notice that 31.25 is greater than 10 (10^1) and less than 100 (10^2). The value for log 31.25 is accordingly between log 10 and log 100, that is, between 1 and 2.

Significant Figures and Common Logarithms

For the common logarithm of a measured quantity, the number of digits after the decimal point equals the number of significant figures in the original number. For example, if 23.5 is a measured quantity (three significant figures), then log 23.5 = 1.371 (three significant figures after the decimal point).

Antilogarithms

The process of determining the number that corresponds to a certain logarithm is known as obtaining an *antilogarithm*. It is the reverse of taking a logarithm. For example, we saw previously that log 23.5 = 1.371. This means that the antilogarithm of 1.371 equals 23.5.

$$\log 23.5 = 1.371$$
$$\text{antilog } 1.371 = 23.5$$

The process of taking the antilog of a number is the same as raising 10 to a power equal to that number.

$$\text{antilog } 1.371 = 10^{1.371} = 23.5$$

Many calculators have a key labeled 10^x that allows you to obtain antilogs directly. On others, it will be necessary to press a key labeled INV (for *inverse*), followed by the LOG key.

Natural Logarithms

Logarithms based on the number e are called natural, or base e, logarithms (abbreviated ln). The natural log of a number is the power to which e (which has the value 2.71828 . . .) must be raised to equal the number. For example, the natural log of 10 equals 2.303.

$$e^{2.303} = 10, \text{ therefore } \ln 10 = 2.303$$

Your calculator probably has a key labeled LN that allows you to obtain natural logarithms. For example, to obtain the natural log of 46.8, you enter 46.8 and press the LN key.

$$\ln 46.8 = 3.846$$

The natural antilog of a number is e raised to a power equal to that number. If your calculator can calculate natural logs, it will also be able to calculate natural antilogs. On some calculators there is a key labeled e^x that allows you to calculate natural antilogs directly; on others, it will be necessary to first press the INV key followed by the LN key. For example, the natural antilog of 1.679 is given by

$$\text{Natural antilog } 1.679 = e^{1.679} = 5.36$$

The relation between common and natural logarithms is as follows:

$$\ln a = 2.303 \log a$$

Notice that the factor relating the two, 2.303, is the natural log of 10, which we calculated earlier.

Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms follow the rules for the use of exponents. For example, the product of z^a and z^b (where z is any number) is given by

$$z^a \cdot z^b = z^{(a+b)}$$

Similarly, the logarithm (either common or natural) of a product equals the *sum* of the logs of the individual numbers.

$$\log ab = \log a + \log b \qquad \ln ab = \ln a + \ln b$$

For the log of a quotient,

$$\log(a/b) = \log a - \log b \qquad \ln(a/b) = \ln a - \ln b$$

Using the properties of exponents, we can also derive the rules for the logarithm of a number raised to a certain power.

$$\log a^n = n \log a \qquad \ln a^n = n \ln a$$

$$\log a^{1/n} = (1/n)\log a \qquad \ln a^{1/n} = (1/n)\ln a$$

pH Problems

One of the most frequent uses for common logarithms in general chemistry is in working pH problems. The pH is defined as $-\log[\mathrm{H^+}]$, where $[\mathrm{H^+}]$ is the hydrogen ion concentration of a solution. (Section 16.4) The following sample exercise illustrates this application.

Sample Exercise 2

Using Logarithms

(**a**) What is the pH of a solution whose hydrogen ion concentration is 0.015 *M*?
(**b**) If the pH of a solution is 3.80, what is its hydrogen ion concentration?

SOLUTION

(**1**) We are given the value of $[H^+]$. We use the LOG key of our calculator to calculate the value of $\log[H^+]$. The pH is obtained by changing the sign of the value obtained. (Be sure to change the sign *after* taking the logarithm.)

$$[H^+] = 0.015$$

$$\log[H^+] = -1.82 \quad (2\text{ significant figures})$$

$$pH = -(-1.82) = 1.82$$

(**2**) To obtain the hydrogen ion concentration when given the pH, we must take the antilog of $-pH$.

$$pH = -\log[H^+] = 3.80$$

$$\log[H^+] = -3.80$$

$$[H^+] = \text{antilog}(-3.80) = 10^{-3.80} = 1.6 \times 10^{-4}\,M$$

Practice Exercise

Perform the following operations:
(**a**) $\log(2.5 \times 10^{-5})$
(**b**) ln 32.7
(**c**) antilog -3.47
(**d**) $e^{-1.89}$

A.3 | Quadratic Equations

An algebraic equation of the form $ax^2 + bx + c = 0$ is called a *quadratic equation*. The two solutions to such an equation are given by the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Many calculators today can calculate the solutions to a quadratic equation with one or two keystrokes. Most of the time, x corresponds to the concentration of a chemical species in solution. Only one of the solutions will be a positive number, and that is the one you should use; a "negative concentration" has no physical meaning.

Sample Exercise 3

Using the Quadratic Formula

Find the values of x that satisfy the equation $2x^2 + 4x = 1$.

SOLUTION

To solve the given equation for x, we must first put it in the form

$$ax^2 + bx + c = 0$$

and then use the quadratic formula. If

$$2x^2 + 4x = 1$$

then

$$2x^2 + 4x - 1 = 0$$

Using the quadratic formula, where $a = 2$, $b = 4$, and $c = -1$, we have

$$x = \frac{-4 \pm \sqrt{4^2 - 4(2)(-1)}}{2(2)}$$

$$= \frac{-4 \pm \sqrt{16 + 8}}{4} = \frac{-4 \pm \sqrt{24}}{4} = \frac{-4 \pm 4.899}{4}$$

The two solutions are

$$x = \frac{0.899}{4} = 0.225 \quad \text{and} \quad x = \frac{-8.899}{4} = -2.225$$

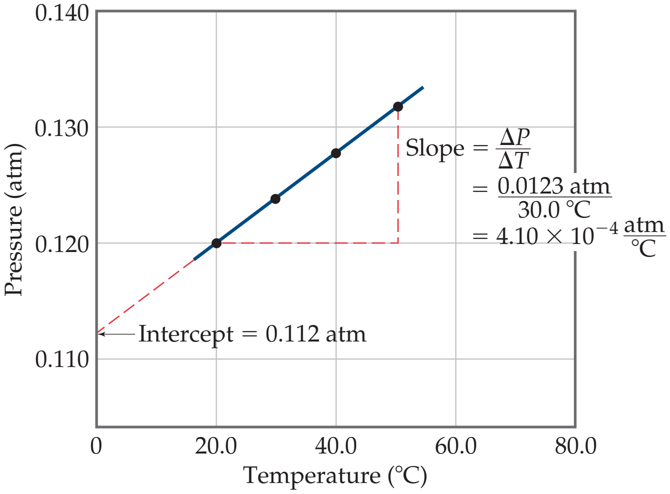
If this was a problem in which x represented a concentration, we would say $x = 0.225$ (in the appropriate units), since a negative number for concentration has no physical meaning.

A.4 | Graphs

Often the clearest way to represent the interrelationship between two variables is to graph them. Usually, the variable that is being experimentally varied, called the *independent variable*, is shown along the horizontal axis (x-axis). The variable that responds

TABLE A.1 Interrelation between Pressure and Temperature

Temperature (°C)	Pressure (atm)
20.0	0.120
30.0	0.124
40.0	0.128
50.0	0.132



▲ **Figure A.1** **A graph of pressure versus temperature yields a straight line for the data.**

to the change in the independent variable, called the *dependent variable*, is then shown along the vertical axis (y-axis). For example, consider an experiment in which we vary the temperature of an enclosed gas and measure its pressure. The independent variable is temperature and the dependent variable is pressure. The data shown in **Table A.1** can be obtained by means of this experiment. These data are shown graphically in **Figure A.1**. The relationship between temperature and pressure is linear. The equation for any straight-line graph has the form

$$y = mx + b$$

where m is the slope of the line and b is the intercept with the y-axis. In the case of Figure A.1, we could say that the relationship between temperature and pressure takes the form

$$P = mT + b$$

where P is pressure in atm and T is temperature in °C. As shown in Figure A.1, the slope is 4.10×10^{-4} atm/°C, and the intercept—the point where the line crosses the y-axis—is 0.112 atm. Therefore, the equation for the line is

$$P = \left(4.10 \times 10^{-4} \frac{\text{atm}}{°\text{C}}\right) T + 0.112 \text{ atm}$$

A.5 | Standard Deviation

The standard deviation from the mean, s, is a common method for describing precision in experimentally determined data. We define the standard deviation as

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \bar{x})^2}{N - 1}}$$

where N is the number of measurements, $\bar{x}$ is the average (also called the mean) of the measurements, and x_i represent the individual measurements. Electronic calculators with built-in statistical functions can calculate s directly by inputting the individual measurements.

A smaller value of s indicates a higher precision, meaning that the data are more closely clustered around the average. The standard deviation has statistical significance. If a large number of measurements is made, 68% of the measured values is expected to be within one standard deviation of the average, assuming only random errors are associated with the measurements.

Sample Exercise 4

Calculating an Average and Standard Deviation

The percent carbon in a sugar is measured four times: 42.01%, 42.28%, 41.79%, and 42.25%. Calculate (**a**) the average and (**b**) the standard deviation for these measurements.

SOLUTION

(**a**) The average is found by adding the quantities and dividing by the number of measurements:

$$\bar{x} = \frac{42.01 + 42.28 + 41.79 + 42.25}{4} = \frac{168.33}{4} = 42.08$$

(**b**) The standard deviation is found using the preceding equation:

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \bar{x})^2}{N - 1}}$$

Let's tabulate the data so the calculation of $\sum_{i=1}^{N}(x_i - \bar{x})^2$ can be seen clearly.

Percent C	Difference between Measurement and Average, $(x_i - x)$	Square of Difference, $(x_i - x)^2$
42.01	$42.01 - 42.08 = -0.07$	$(-0.07)^2 = 0.005$
42.28	$42.28 - 42.08 = 0.20$	$(0.20)^2 = 0.040$
41.79	$41.79 - 42.08 = -0.29$	$(-0.29)^2 = 0.084$
42.25	$42.25 - 42.08 = 0.17$	$(0.17)^2 = 0.029$

The sum of the quantities in the last column is

$$\sum_{i=1}^{N}(x_i - \bar{x})^2 = 0.005 + 0.040 + 0.084 + 0.029 = 0.16$$

Thus, the standard deviation is

$$s = \sqrt{\frac{\sum_{i=1}^{N}(x_i - \bar{x})^2}{N - 1}} = \sqrt{\frac{0.16}{4 - 1}} = \sqrt{\frac{0.16}{3}} = \sqrt{0.053} = 0.23$$

Based on these measurements, it would be appropriate to represent the measured percent carbon as 42.08 ± 0.23.

D

AQUEOUS EQUILIBRIUM CONSTANTS

TABLE D.1 **Dissociation Constants for Acids at 25 °C**

Name	Formula	K_{a1}	K_{a2}	K_{a3}
Acetic acid	CH_3COOH (or $HC_2H_3O_2$)	1.8×10^{-5}		
Arsenic acid	H_3AsO_4	5.6×10^{-3}	1.0×10^{-7}	3.0×10^{-12}
Arsenous acid	H_3AsO_3	5.1×10^{-10}		
Ascorbic acid	$H_2C_6H_6O_6$	8.0×10^{-5}	1.6×10^{-12}	
Benzoic acid	C_6H_5COOH (or $HC_7H_5O_2$)	6.3×10^{-5}		
Boric acid	H_3BO_3	5.8×10^{-10}		
Butanoic acid	C_3H_7COOH (or $HC_4H_7O_2$)	1.5×10^{-5}		
Carbonic acid	H_2CO_3	4.3×10^{-7}	5.6×10^{-11}	
Chloroacetic acid	$CH_2ClCOOH$ (or $HC_2H_2O_2Cl$)	1.4×10^{-3}		
Chlorous acid	$HClO_2$	1.0×10^{-2}		
Citric acid	$HOOCC(OH)(CH_2COOH)_2$ (or $H_3C_6H_5O_7$)	7.4×10^{-4}	1.7×10^{-5}	4.0×10^{-7}
Cyanic acid	$HCNO$	3.5×10^{-4}		
Formic acid	$HCOOH$ (or $HCHO_2$)	1.8×10^{-4}		
Hydroazoic acid	HN_3	1.9×10^{-5}		
Hydrocyanic acid	HCN	4.9×10^{-10}		
Hydrofluoric acid	HF	6.8×10^{-4}		
Hydrogen chromate ion	$HCrO_4^-$	3.0×10^{-7}		
Hydrogen peroxide	H_2O_2	2.4×10^{-12}		
Hydrogen selenate ion	$HSeO_4^-$	2.2×10^{-2}		
Hydrogen sulfide	H_2S	9.5×10^{-8}	1×10^{-19}	
Hypobromous acid	$HBrO$	2.5×10^{-9}		
Hypochlorous acid	$HClO$	3.0×10^{-8}		
Hypoiodous acid	HIO	2.3×10^{-11}		
Iodic acid	HIO_3	1.7×10^{-1}		
Lactic acid	$CH_3CH(OH)COOH$ (or $HC_3H_5O_3$)	1.4×10^{-4}		
Malonic acid	$CH_2(COOH)_2$ (or $H_2C_3H_2O_4$)	1.5×10^{-3}	2.0×10^{-6}	
Nitrous acid	HNO_2	4.5×10^{-4}		
Oxalic acid	$(COOH)_2$ (or $H_2C_2O_4$)	5.9×10^{-2}	6.4×10^{-5}	
Paraperiodic acid	H_5IO_6	2.8×10^{-2}	5.3×10^{-9}	
Phenol	C_6H_5OH (or HC_6H_5O)	1.3×10^{-10}		
Phosphoric acid	H_3PO_4	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
Propionic acid	C_2H_5COOH (or $HC_3H_5O_2$)	1.3×10^{-5}		
Pyrophosphoric acid	$H_4P_2O_7$	3.0×10^{-2}	4.4×10^{-3}	2.1×10^{-7}
Selenous acid	H_2SeO_3	2.3×10^{-3}	5.3×10^{-9}	
Sulfuric acid	H_2SO_4	Strong acid	1.2×10^{-2}	
Sulfurous acid	H_2SO_3	1.7×10^{-2}	6.4×10^{-8}	
Tartaric acid	$HOOC(CHOH)_2COOH$ (or $H_2C_4H_4O_6$)	1.0×10^{-3}	1.4×10^{-5}	

TABLE D.2 Dissociation Constants for Bases at 25 °C

Name	Formula	K_b
Ammonia	NH_3	1.8×10^{-5}
Aniline	$C_6H_5NH_2$	4.3×10^{-10}
Dimethylamine	$(CH_3)_2NH$	5.4×10^{-4}
Ethylamine	$C_2H_5NH_2$	6.4×10^{-4}
Hydrazine	H_2NNH_2	1.3×10^{-6}
Hydroxylamine	$HONH_2$	1.1×10^{-8}
Methylamine	CH_3NH_2	4.4×10^{-4}
Pyridine	C_5H_5N	1.7×10^{-9}
Trimethylamine	$(CH_3)_3N$	6.4×10^{-5}

TABLE D.3 Solubility-Product Constants for Compounds at 25 °C

Name	Formula	K_{sp}	Name	Formula	K_{sp}
Barium carbonate	$BaCO_3$	5.0×10^{-9}	Lead(II) fluoride	PbF_2	3.6×10^{-8}
Barium chromate	$BaCrO_4$	2.1×10^{-10}	Lead(II) sulfate	$PbSO_4$	6.3×10^{-7}
Barium fluoride	BaF_2	1.7×10^{-6}	Lead(II) sulfide*	PbS	3×10^{-28}
Barium oxalate	BaC_2O_4	1.6×10^{-6}	Magnesium hydroxide	$Mg(OH)_2$	1.8×10^{-11}
Barium sulfate	$BaSO_4$	1.1×10^{-10}	Magnesium carbonate	$MgCO_3$	3.5×10^{-8}
Cadmium carbonate	$CdCO_3$	1.8×10^{-14}	Magnesium oxalate	MgC_2O_4	8.6×10^{-5}
Cadmium hydroxide	$Cd(OH)_2$	2.5×10^{-14}	Manganese(II) carbonate	$MnCO_3$	5.0×10^{-10}
Cadmium sulfide*	CdS	8×10^{-28}	Manganese(II) hydroxide	$Mn(OH)_2$	1.6×10^{-13}
Calcium carbonate (calcite)	$CaCO_3$	4.5×10^{-9}	Manganese(II) sulfide*	MnS	2×10^{-53}
Calcium chromate	$CaCrO_4$	7.1×10^{-4}	Mercury(I) chloride	Hg_2Cl_2	1.2×10^{-18}
Calcium fluoride	CaF_2	3.9×10^{-11}	Mercury(I) iodide	Hg_2I_2	$1.1 \times 10^{-1.1}$
Calcium hydroxide	$Ca(OH)_2$	6.5×10^{-6}	Mercury(II) sulfide*	HgS	2×10^{-53}
Calcium phosphate	$Ca_3(PO_4)_2$	2.0×10^{-29}	Nickel(II) carbonate	$NiCO_3$	1.3×10^{-7}
Calcium sulfate	$CaSO_4$	2.4×10^{-5}	Nickel(II) hydroxide	$Ni(OH)_2$	6.0×10^{-16}
Chromium(III) hydroxide	$Cr(OH)_3$	6.7×10^{-31}	Nickel(II) sulfide*	NiS	3×10^{-20}
Cobalt(II) carbonate	$CoCO_3$	1.0×10^{-10}	Silver bromate	$AgBrO_3$	5.5×10^{-13}
Cobalt(II) hydroxide	$Co(OH)_2$	1.3×10^{-15}	Silver bromide	$AgBr$	5.0×10^{-13}
Cobalt(II) sulfide*	CoS	5×10^{-22}	Silver carbonate	Ag_2CO_3	8.1×10^{-12}
Copper(I) bromide	$CuBr$	5.3×10^{-9}	Silver chloride	$AgCl$	1.8×10^{-10}
Copper(II) carbonate	$CuCO_3$	2.3×10^{-10}	Silver chromate	Ag_2CrO_4	1.2×10^{-12}
Copper(II) hydroxide	$Cu(OH)_2$	4.8×10^{-20}	Silver iodide	AgI	8.3×10^{-17}
Copper(II) sulfide*	CuS	6×10^{-37}	Silver sulfate	Ag_2SO_4	1.5×10^{-5}
Iron(II) carbonate	$FeCO_3$	2.1×10^{-11}	Silver sulfide*	Ag_2S	6×10^{-51}
Iron(II) hydroxide	$Fe(OH)_2$	7.9×10^{-16}	Strontium carbonate	$SrCO_3$	9.3×10^{-10}
Lanthanum fluoride	LaF_3	2×10^{-19}	Tin(II) sulfide*	SnS	1×10^{-26}
Lanthanum iodate	$La(IO_3)_3$	7.4×10^{-14}	Zinc carbonate	$ZnCO_3$	1.0×10^{-10}
Lead(II) carbonate	$PbCO_3$	7.4×10^{-14}	Zinc hydroxide	$Zn(OH)_2$	3.0×10^{-16}
Lead(II) chloride	$PbCl_2$	1.7×10^{-5}	Zinc oxalate	ZnC_2O_4	2.7×10^{-8}
Lead(II) chromate	$PbCrO_4$	2.8×10^{-13}	Zinc sulfide*	ZnS	2×10^{-25}

*For a solubility equilibrium of the type $MS(s) + H_2O(l) \rightleftharpoons M^{2+}(aq) + HS^-(aq) + OH^-(aq)$

ANSWERS TO RED EXERCISES

Answers to Go Figures, Practice Exercises, and Self Assessment Exercises are available as PDF files within Mastering Chemistry. We invite instructors to share these resources as needed.

Chapter 1

1.1 (**a**) Four (**b**) six (**c**) hydrogen (**d**) 22 **1.2** (**a**) Pure element: i (**b**) mixture of elements: v, vi (**c**) pure compound: iv (**d**) mixture of an element and a compound: ii, iii **1.4** (**a**) Homogeneous mixture (**b**) Yes, brass is a solution. **1.5** (**iv**) A gas is turning into a solid. **1.7** Filtration **1.8** (**a**) The aluminum sphere is lightest, then nickel, then silver. (**b**) The platinum cube is smallest, then gold, then lead. **1.10** (**a**) 7.5 cm; two significant figures (sig figs) (**b**) 72 mi/hr (inner scale, two sig figs) or 115 km/hr (outer scale, three sig figs) **1.12** 464 jelly beans. The mass of an average bean has 2 decimal places and 3 sig figs. The number of beans then has 3 sig figs, by the rules for multiplication and division. **1.13** Statement (c) is false. **1.15** (**a**) Heterogeneous mixture (**b**) homogeneous mixture (heterogeneous if there are undissolved particles) (**c**) pure substance (**d**) pure substance. **1.17** (**a**) S (**b**) Au (**c**) K (**d**) Cl (**e**) Cu (**f**) uranium (**g**) nickel (**h**) sodium (**i**) aluminum (**j**) silicon **1.19** C is a compound; it contains both carbon and oxygen. A is a compound; it contains at least carbon and oxygen. B is not defined by the data given; it is probably also a compound because few elements exist as white solids. **1.21** Physical properties: silvery white; lustrous; melting point = 649 °C, boiling point = 1105 °C; density at 20 °C = 1.738 g/cm^3; pounded into sheets; drawn into wires; good conductor. Chemical properties: burns in air; reacts with Cl_2. **1.23** (**a**) Chemical (**b**) physical (**c**) physical (**d**) chemical (**e**) chemical **1.25** (**a**) Filtration (**b**) chromatography (**c**) distillation **1.27** Statements (i) and (iii) are true. **1.29** (**a**) 1.9×10^5 J (**b**) 4.6×10^4 cal (**c**) 14 m/s **1.31** (**a**) Kinetic energy (**b**) Potential energy decreases. (**c**) increase **1.33** (**a**) 1×10^{-1} (**b**) 1×10^{-2} (**c**) 1×10^{-15} (**d**) 1×10^{-6} (**e**) 1×10^{6} (**f**) 1×10^{3} (**g**) 1×10^{-9} (**h**) 1×10^{-3} (**i**) 1×10^{-12} **1.35** (**a**) 22 °C (**b**) 422.1 °F (**c**) 506 K (**d**) 107 °F (**e**) 1600 K (**f**) −459.67 °F **1.37** (**a**) 1.62 g/mL. Tetrachloroethylene, 1.62 g/mL, is more dense than water, 1.00 g/mL; tetrachloroethylene will sink rather than float on water. (**b**) 11.7 **g** **1.39** (**a**) Calculated density = 0.86 g/mL. The substance is probably toluene, density = 0.866 g/mL. (**b**) 89.2 mL benzene (**c**) 1.11×10^3 g nickel **1.41** (**a**) 940 Tg (**b**) 1.1×10^{11} gal gasoline (**c**) 520 teraliters (TL) of CO_2 **1.43** Exact: (b), (d), and (f) **1.45** (**a**) 2 (**b**) 4 (**c**) 4 (**d**) 3 (**e**) 3 (**f**) 1 **1.47** (**a**) 1.025×10^2 (**b**) 6.570×10^2 (**c**) 8.543×10^{-3} (**d**) 2.579×10^{-4} (**e**) -3.572×10^{-2} **1.49** (**a**) 17.00 (**b**) 812.0 (**c**) 8.23×10^3 (**d**) 8.69×10^{-2} **1.51** (**a**) 3.80×10^5 (**b**) 7.91×10^6 (**c**) 1.68×10^2 (**d**) −9.45 **1.53** 5 significant figures

1.55 (**a**) $\frac{1 \times 10^{-3}\ \text{m}}{1\ \text{mm}} \times \frac{1\ \text{nm}}{1 \times 10^{-9}\ \text{m}}$ (**b**) $\frac{1 \times 10^{-3}\ \text{g}}{1\ \text{mg}} \times \frac{1\ \text{kg}}{1000\ \text{g}}$ (**c**) $\frac{1000\ \text{m}}{1\ \text{km}} \times \frac{1\ \text{cm}}{1 \times 10^{-2}\ \text{m}} \times \frac{1\ \text{in.}}{2.54\ \text{cm}} \times \frac{1\ \text{ft}}{12\ \text{in.}}$ (**d**) $\frac{(2.54)^3\ \text{cm}^3}{1^3\ \text{in.}^3}$

1.57 (**a**) 54.7 km/hr (**b**) 1.3×10^3 gal (**c**) 46.0 m (**d**) 0.984 in/hr **1.59** (**a**) 4.32×10^5 s (**b**) 88.5 m (**c**) \$0.499/L (**d**) 46.6 km/hr (**e**) 1.420 L/s (**f**) 707.9 cm^3 **1.61** (**a**) 1.2×10^2 L (**b**) 5×10^2 mg (**c**) 19.9 mi/gal (2×10^1 mi/gal for 1 significant figure) (**d**) 1.81 kg **1.63** 0.18 g CO **1.65** (**a**) 1208 lb/ft^3 (**b**) 232.2 g **1.67** \$1 $\times 10^5$ **1.71** 8.47 g O **1.73** (**a**) Set 1, 34.44; set 2, 34.52. Based on the average, set 1 is more accurate. (**b**) The average deviation for set 1 is 0.02 and for set 2 is 0.03. Set 1 is more precise. **1.74** (**a**) Volume (**b**) area (**c**) volume (**d**) density (**e**) time (**f**) length (**g**) temperature **1.78** Substances (**c**), (**d**), (**e**), (**g**) and (**h**) are pure or nearly pure. **1.80** (**a**) 1.13×10^5 quarters (**b**) 6.41×10^5 g (**c**) \$$2.83 \times 10^4$ (**d**) 9.28×10^8 stacks **1.84** The most dense liquid, Hg, will sink; the least dense, cyclohexane, will float; H_2O will be in the middle. **1.88** density of solid = 1.63 g/mL **1.94** The inner diameter of the tube is 1.71 cm. **1.96** Statements (i) and (iii) are true. **1.99** (**a**) Volume = 0.050 mL (**b**) surface area = 12.4 m^2 (**c**) 99.99% of the mercury was removed. (**d**) The spongy material weighs 17.7 mg after exposure to mercury.

Chapter 2

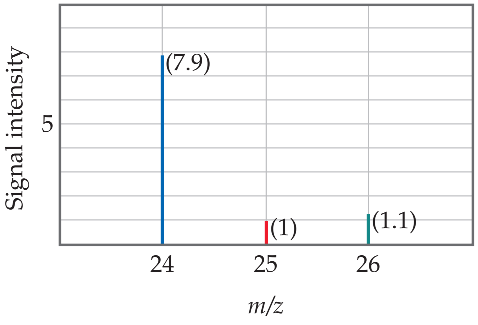
2.1 (**a**) (−) (**b**) increase (**c**) decrease **2.4** The particle is an ion. ${}^{32}_{16}S^{2-}$ **2.6** Formula: IF_5; name: iodine pentafluoride; the compound is molecular. **2.8** Only $Ca(NO_3)_2$, calcium nitrate, is consistent with the diagram. **2.10** (**a**) In the presence of an electric field, there is electrostatic attraction between the negatively charged oil drops and the positively charged plate as well as electrostatic repulsion between the negatively charged oil drops and the negatively charged plate. These electrostatic forces oppose the force of gravity and change the rate of fall of the drops. (**b**) Each individual drop has a different number of electrons associated with it. If the combined electrostatic forces are greater than the force of gravity, the drop moves up. **2.11** (**a**) mass O/mass C = 2.66 (**b**) mass O/mass C = 1.33 (**c**) CO **2.13** (**a**) 0.5711 g O/1 g N; 1.142 g O/1 g N; 2.284 g O/1 g N; 2.855 g O/1 g N (**b**) The numbers in part (**a**) obey the *law of multiple proportions*. Multiple proportions arise because atoms are the indivisible entities combining, as stated in Dalton's atomic theory. **2.15** Neutrons were discovered last. **2.17** (a) is correct – only statement (i) is true. **2.19** (**a**) 0.135 nm; 1.35×10^2 or 135 pm (**b**) 3.70×10^6 Au atoms (**c**) 1.03×10^{-23} cm^3 **2.21** (**a**) Proton, neutron, electron (**b**) proton = 1+, neutron = 0, electron = 1− (**c**) The neutron is most massive. (The neutron and proton have very similar masses.) (**d**) The electron is least massive. **2.23** (**a**) 5 protons, 5 neutrons, 5 electrons (**b**) ${}^{11}_{6}C$ (**c**) ${}^{11}_{5}B$ (**d**) The atom in part (**c**) is an isotope of ${}^{10}B$. **2.25** (**a**) Atomic number is the number of protons in the nucleus of an atom. Mass number is the total number of nuclear particles, protons plus neutrons, in an atom. (**b**) atomic number (**c**) mass number **2.27** (**a**) ${}^{40}Ar$: 18 p, 22 n, 18 e (**b**) ${}^{65}Zn$: 30 p, 35 n, 30 e (**c**) ${}^{70}Ga$: 31 p, 39 n, 31 e (**d**) ${}^{80}Br$: 35 p, 45 n, 35 e (**e**) ${}^{184}W$: 74 p, 110 n, 74 e (**f**) ${}^{243}Am$: 95 p, 148 n, 95e

2.29

Symbol	${}^{79}Br$	${}^{55}Mn$	${}^{112}Cd$	${}^{222}Rn$	${}^{207}Pb$
Protons	35	25	48	86	82
Neutrons	44	30	64	136	125
Electrons	35	25	48	86	82
Mass no.	79	55	112	222	207

2.31 (**a**) ${}^{196}_{78}Pt$ (**b**) ${}^{84}_{36}Kr$ (**c**) ${}^{75}_{33}As$ (**d**) ${}^{24}_{12}Mg$ **2.33** Answer (b) is the best choice. Each B atom will have the mass of one of the naturally occurring isotopes, while the "atomic weight" is an average value. **2.35** 63.55 amu **2.37** (**a**) In Thomson's cathode ray tube, the charged particles are electrons. In a mass spectrometer, the charged particles are positively charged ions (cations). (**b**) The *x*-axis label is *m/z* (the ratio of mass to charge of the particles) and the *y*-axis label is signal intensity. (**c**) The Cl^{2+}ion will be deflected more. **2.39** (**a**) average atomic mass = 24.31 amu

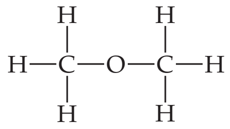
(**b**)



2.41 (**a**) Cr, 24 (metal) (**b**) He, 2 (nonmetal) (**c**) P, 15 (nonmetal) (**d**) Zn, 30 (metal) (**e**) Mg, 12 (metal) (**f**) Br, 35 (nonmetal) (**g**) As, 33 (metalloid) **2.43** (**a**) K, alkali metals (metal) (**b**) I, halogens (nonmetal) (**c**) Mg, alkaline earth metals (metal) (**d**) Ar, noble gases (nonmetal) (**e**) S, chalcogens (nonmetal) **2.45** (**a**) C_4H_{10} is the molecular formula for both compounds. (**b**) C_2H_5 is the empirical formula for both compounds. (**c**) structural **2.47** From left to right: molecular, N_2H_4, empirical, NH_2; molecular, N_2H_2, empirical, NH, molecular and empirical, NH_3 **2.49** (**a**) $AlBr_3$ (**b**) C_4H_5 (**c**) C_2H_4O (**d**) P_2O_5 (**e**) C_3H_2Cl (**f**) BNH_2 **2.51** (**a**) 6 (**b**) 10 (**c**) 12

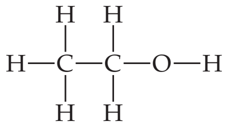
2.53

(**a**) C_2H_6O,



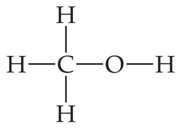
$\mathrm{H-\underset{H}{\overset{H}{C}}-O-\underset{H}{\overset{H}{C}}-H}$

(**b**) C_2H_6O,



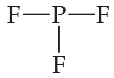
$\mathrm{H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-O-H}$

(**c**) CH_4O,



$\mathrm{H-\underset{H}{\overset{H}{C}}-O-H}$

(**d**) PF_3,



$\mathrm{F-\underset{F}{P}-F}$

2.55

Symbol	$^{59}CO^{3+}$	$^{80}Se^{2-}$	$^{192}OS^{2+}$	$^{200}Hg^{2+}$
Protons	27	34	76	80
Neutrons	32	46	116	120
Electrons	24	36	74	78
Net Charge	3+	2−	2+	2+

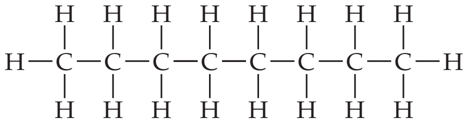
2.57 (**a**) Mg^{2+} (**b**) Al^{3+} (**c**) K^+ (**d**) S^{2-} (**e**) F^- **2.59** (**a**) GaF_3, gallium(III) fluoride (**b**) LiH, lithium hydride (**c**) AlI_3, aluminum iodide (**d**) K_2S, potassium sulfide **2.61** (**a**) $CaBr_2$ (**b**) K_2CO_3 (**c**) $Al(CH_3COO)_3$ (**d**) $(NH_4)_2SO_4$ (**e**) $Mg_3(PO_4)_2$

2.63

Ion	K^+	NH_4^+	Mg^{2+}	Fe^{3+}
CI^-	KCl	NH_4C1	$MgC1_2$	$FeC1_3$
OH^-	KOH	NH_4OH	$Mg(OH)_2$	$Fe(OH)_3$
CO_3^{2-}	K_2CO_3	$(NH_4)_2CO_3$	$MgCO_3$	$Fe_2(CO_3)_3$
PO_4^{3-}	K_3PO_4	$(NH_4)_3PO_4$	$Mg_3(PO_4)_2$	$FePO_4$

2.65 Molecular: (**a**) B_2H_6 (**b**) CH_3OH (**f**) NOCl (**g**) NF_3. Ionic: (**c**) $LiNO_3$ (**d**) Sc_2O_3 (**e**) CsBr (**f**) Ag_2SO_4 **2.67** (**a**) ClO_2^- (**b**) Cl^- (**c**) ClO_3^- (**d**) ClO_4^- (**e**) ClO^- **2.69** (**a**) calcium, 2+; oxide, 2− (**b**) sodium, 1+; sulfate, 2− (**c**) potassium, 1+; perchlorate, 1− (**d**) iron, 2+, nitrate, 1− (**e**) chromium, 3+; hydroxide, 1− **2.71** (**a**) lithium oxide (**b**) iron(III) chloride (ferric chloride) (**c**) sodium hypochlorite (**d**) calcium sulfite (**e**) copper(II) hydroxide (cupric hydroxide) (**f**) iron(II) nitrate (ferrous nitrate) (**g**) calcium acetate (**h**) chromium(III) carbonate (chromic carbonate) (**i**) potassium chromate (**j**) ammonium sulfate **2.73** (**a**) $Al(OH)_3$ (**b**) K_2SO_4 (**c**) Cu_2O (**d**) $Zn(NO_3)_2$ (**e**) $HgBr_2$ (**f**) $Fe_2(CO_3)_3$ (**g**) NaBrO **2.75** (**a**) Bromic acid (**b**) hydrobromic acid (**c**) phosphoric acid (**d**) HClO (**e**) HIO_3 (**f**) H_2SO_3 **2.77** (**a**) Sulfur hexafluoride (**b**) selenium dichloride (**c**) xenon trioxide (**d**) N_2O_4 (**e**) HCN (**f**) P_4S_6 **2.79** (**a**) $ZnCO_3$, ZnO, CO_2 (**b**) HF, SiO_2, SiF_4, H_2O (**c**) SO_2, H_2O, H_2SO_3 (**d**) PH_3 (**e**) $HClO_4$, Cd, $Cd(ClO_4)_2$ (**f**) VBr_3 **2.81** (**a**) A hydrocarbon is a compound composed of the elements hydrogen and carbon only.

(**b**)

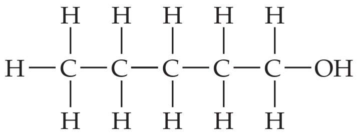


$\mathrm{H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-H}$

molecular formula C_8H_{18}, empirical formula C_4H_9

2.83 (**a**) —OH

(**b**)



$\mathrm{H-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-\underset{H}{\overset{H}{C}}-OH}$

2.85 The correct answer is (c). The incorrect formula for methanol, CH_4OH, should be corrected to CH_3OH. **2.87** Structures c and d are the same molecule. **2.89** (**a**) 2-methylhexane (**b**) 4-ethyl-2, 4-dimethyldecane (**c**) $CH_3CH_2CH_2CH_2CH_2CH(CH_3)_2$ (**d**) $CH_3CH_2CH_2CH_2CH(CH_2CH_3)CH(CH_3)CH(CH_3)_2$ **2.91** Statement (d) is correct. **2.94** (**a**) 2 protons, 1 neutron, 2 electrons (**b**) tritium, ^3H, is more massive. (**c**) A precision of 1×10^{-27} g would be required to differentiate between $^3H^+$ and $^3He^+$. **2.97** (**a**) $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$ (**b**) None of them contain 10 electrons; they all have 8. (**c**) 9 **2.99** (**a**) $^{69}_{31}Ga$, 31 protons, 38 neutrons; $^{71}_{31}Ga$, 31 protons, 40 neutrons (**b**) $^{69}_{31}Ga$, 60.3%, $^{71}_{31}Ga$, 39.7%. **2.101** (**a**) 5 significant figures (**b**) An electron is 0.05444% of the mass of an ^1H atom. **2.106** (**a**) nickel(II) oxide, 2+ (**b**) manganese(IV) oxide, 4+ (**c**) chromium(III) oxide, 3+ (**d**) molybdenum(VI) oxide, 6+ **2.109** (**a**) Perbromate ion (**b**) selenite ion (**c**) AsO_4^{3-} (**d**) $HTeO_4^-$ **2.112** (**a**) Potassium nitrate (**b**) sodium carbonate (**c**) calcium oxide (**d**) hydrochloric acid (**e**) magnesium sulfate (**f**) magnesium hydroxide

Chapter 3

3.1 Equation (**a**) best fits the diagram. **3.3** (**a**) NO_2 (**b**) No, because we have no way of knowing whether the empirical and molecular formulas are the same. NO_2 represents the simplest ratio of atoms in a molecule but not the only possible molecular formula. **3.5** (**a**) $C_2H_5NO_2$ (**b**) 75.0 g/mol (**c**) 1.332 mol glycine (**d**) Mass %N in glycine is 18.7%. **3.7** (**a**) $N_2 + 3H_2 \longrightarrow 2\,NH_3$. (**b**) H_2 is the limiting reactant. (**c**) 6 NH_3 molecules can be made. (**d**) One N_2 molecule is left over. **3.9** (**a**) False (**b**) true (**c**) false

3.11 (**a**) $2\,CO(g) + O_2(g) \longrightarrow 2\,CO_2(g)$
(**b**) $N_2O_5(g) + H_2O(l) \longrightarrow 2\,HNO_3(aq)$
(**c**) $CH_4(g) + 4\,Cl_2(g) \longrightarrow CCl_4(l) + 4\,HCl(g)$
(**d**) $Zn(OH)_2(s) + 2\,HNO_3(aq) \longrightarrow Zn(NO_3)_2(aq) + 2\,H_2O(l)$
3.13 (**a**) $A1_4C_3(s) + 12\,H_2O(l) \longrightarrow 4\,A1(OH)_3(s) + 3\,CH_4(g)$
(**b**) $2\,C_5H_{10}O_2(l) + 13\,O_2(g) \longrightarrow 10\,CO_2(g) + 10\,H_2O(g)$
(**c**) $2\,Fe(OH)_3(s) + 3\,H_2SO_4(aq) \longrightarrow Fe_2(SO_4)_3(aq) + 6\,H_2O(l)$
(**d**) $Mg_3N_2(s) + 4\,H_2SO_4(aq) \longrightarrow 3\,MgSO_4(aq) + (NH_4)_2SO_4(aq)$

3.15 (**a**) $CaC_2(s) + 2\,H_2O(l) \longrightarrow Ca(OH)_2(aq) + C_2H_2(g)$
(**b**) $2\,KClO_3(s) \xrightarrow{\Delta} 2\,KCl(s) + 3\,O_2(g)$
(**c**) $Zn(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2(g)$
(**d**) $PCl_3(l) + 3\,H_2O(l) \longrightarrow H_3PO_3(aq) + 3\,HCl(aq)$
(**e**) $3\,H_2S(g) + 2\,Fe(OH)_3(s) \longrightarrow Fe_2S_3(s) + 6\,H_2O(g)$
3.17 (**a**) NaBr (**b**) solid (**c**) 2 **3.19** (**a**) $Mg(s) + Cl_2(g) \longrightarrow MgCl_2(s)$
(**b**) $BaCO_3(s) \xrightarrow{\Delta} BaO(s) + CO_2(g)$
(**c**) $C_8H_8(l) + 10\,O_2(g) \longrightarrow 8\,CO_2(g) + 4\,H_2O(l)$
(**d**) $C_2H_6O(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(l)$
3.21 (**a**) $2\,C_3H_6(g) + 9\,O_2(g) \longrightarrow 6\,CO_2(g) + 6\,H_2O(g)$ combustion
(**b**) $NH_4NO_3(s) \longrightarrow N_2O(g) + 2\,H_2O(g)$ decomposition
(**c**) $C_5H_6O(l) + 6\,O_2(g) \longrightarrow 5\,CO_2(g) + 3\,H_2O(g)$ combustion

Chapter 4

4.1 Diagram (**c**) represents Li_2SO_4 **4.5** $BaCl_2$ **4.7** (**c**) is correct **4.9** This reaction is (**c**), a redox reaction.
4.13 (**a**) False. Electrolyte solutions conduct electricity because *ions* are moving through the solution. (**b**) True. Because ions are mobile in solution, the added presence of uncharged molecules does not inhibit conductivity. **4.15** Statement (**b**) is most correct.
4.17 (**a**) $FeCl_2(aq) \longrightarrow Fe^{2+}(aq) + 2\,Cl^-(aq)$
(**b**) $HNO_3(aq) \longrightarrow H^+(aq) + NO_3^-(aq)$
(**c**) $(NH_4)_2SO_4(aq) \longrightarrow 2\,NH_4^+(aq) + SO_4^{2-}(aq)$
(**d**) $Ca(OH_4)_2(aq) \longrightarrow Ca^{2+}(aq) + 2\,OH^-(aq)$
4.19 HCOOH molecules, H^+ ions, and $HCOO^-$ ions; $HCOOH(aq) \rightleftharpoons H^+(aq) + HCOO^-(aq)$ **4.21** (**a**) Soluble (**b**) insoluble (**c**) soluble (**d**) soluble (**e**) soluble **4.23** (**a**) $Na_2CO_3(aq) + 2\,AgNO_3(aq) \longrightarrow Ag_2CO_3(s) + 2\,NaNO_3(aq)$ (**b**) No precipitate (**c**) $FeSO_4(aq) + Pb(NO_3)_2(aq) \longrightarrow PbSO_4(s) + Fe(NO_3)_2(aq)$
4.25 (**a**) K^+, SO_4^{2-} (**b**) Li^+, NO_3^- (**c**) NH_4^+, Cl^- **4.27** Only Pb^{2+} could be present. **4.29** Answer (**c**) is correct. **4.31** The 0.20 *M* HI(*aq*) is most acidic (**b**). **4.33** (**a**) False. H_2SO_4 is a diprotic acid; it has two ionizable hydrogen atoms. (**b**) False. HCl is a strong acid. (**c**) False. CH_3OH is a molecular nonelectrolyte. **4.35** (**a**) Acid, mixture of ions and molecules (weak electrolyte) (**b**) none of the above, entirely molecules (nonelectrolyte) (**c**) salt, entirely ions (strong electrolyte) (**d**) base, entirely ions (strong electrolyte) **4.37** (**a**) H_2SO_3, weak electrolyte (**b**) CH_3CH_2OH, nonelectrolyte (**c**) NH_3, weak electrolyte (**d**) $KClO_3$, strong electrolyte (**e**) $Cu(NO_3)_2$, strong electrolyte
4.39 (**a**) $2\,HBr(aq) + Ca(OH)_2(aq) \longrightarrow CaBr(aq) + 2\,H_2O(l)$;
$H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$;
(**b**) $Cu(OH)_2(s) + 2\,HClO_4(aq) \longrightarrow Cu(ClO_4)_2(aq) + 2\,H_2O(l)$;
$Cu(OH)_2(s) + 2\,H^+(aq) \longrightarrow 2\,H_2O(l) + Cu^{2+}(aq)$
(**c**) $Al(OH)_3(s) + 3\,HNO_3(aq) \longrightarrow Al(NO_3)_3(aq) + 3\,H_2O(l)$;
$Al(OH)_3(s) + 3\,H^+(aq) \longrightarrow 3\,H_2O(l) + Al^{3+}(aq)$
4.41 (**a**) $CdS(s) + H_2SO_4(aq) \longrightarrow CdSO_4(aq) + H_2S(g)$;
$CdS(s) + 2H^+(aq) \longrightarrow H_2S(g) + Cd^{2+}(aq)$
(**b**) $MgCO_3(s) + 2\,HClO_4(aq) \longrightarrow Mg(ClO_4)_2(aq) + H_2O(l) + CO_2(g)$;
$MgCO_3(s) + 2\,H^+(aq) \longrightarrow H_2O(l) + CO_2(g) + Mg^{2+}(aq)$
4.43 $MgCO_3(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l) + CO_2(g)$;
$MgCO_3(s) + 2\,H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2O(l) + CO_2(g)$;
$MgO(s) + 2\,HCl(aq) \longrightarrow MgCl_2(aq) + H_2O(l)$;
$MgO(s) + 2\,H^+(aq) \longrightarrow Mg^{2+}(aq) + H_2O(l)$;
$Mg(OH)_2(s) + 2\,H^+(aq) \longrightarrow Mg^{2+}(aq) + 2\,H_2O(l)$
4.45 (**a**) False (**b**) true **4.47** Metals in region A are most easily oxidized. Nonmetals in region D are least easily oxidized.
4.49 (**a**) +4 (**b**) +4 (**c**) +7 (**d**) +1 (**e**) +3 (**f**) −1 **4.51** (**a**) H is oxidized; N is reduced (**b**) Fe is reduced; Al is oxidized (**c**) Cl is reduced; I is oxidized (**d**) S is oxidized; O is reduced
4.53 (**a**) $Sn(s) + 2\,HCl(aq) \longrightarrow SnCl_2(aq) + H_2(g)$;
$Sn(s) + 2\,H^+(aq) \longrightarrow Sn^{2+}(aq) + H_2(g)$
(**b**) $2\,Al(s) + 6\,HCOOH(aq) \longrightarrow 2\,Al(HCOO)_3(aq) + 3\,H_2(g)$;
$2\,Al(s) + 6\,HCOOH(aq) \longrightarrow 2\,Al^{3+}(aq) + 6\,HCOO^-(aq) + 3\,H_2(g)$
4.55 (**a**) $Fe(s) + Cu(NO_3)_2(aq) \longrightarrow Fe(NO_3)_2(aq) + Cu(s)$
(**b**) NR (**c**) $Sn(s) + 2\,HBr(aq) \longrightarrow SnBr_2(aq) + H_2(g)$
(**d**) NR (**e**) $2\,Al(s) + 3\,CoSO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3\,Co(s)$

4.57 (**a**) i. $\mathrm{Zn}(s) + \mathrm{Cd}^{2+}(aq) \longrightarrow \mathrm{Cd}(s) + \mathrm{Zn}^{2+}(aq)$; ii. $\mathrm{Cd}(s) + \mathrm{Ni}^{2+}(aq) \longrightarrow \mathrm{Ni}(s) + \mathrm{Cd}^{2+}(aq)$ (**b**) Cd must be below Zn in the activity series. (**c**) Cd must be above Ni in the activity series. **4.59** (**a**) Intensive; the ratio of amount of solute to total amount of solution is the same, regardless of how much solution is present. (**b**) The term 0.50 mol HCl defines an amount (~18 g) of the pure substance HCl. The term 0.50 *M* HCl is a ratio; it indicates that there is 0.50 mol of HCl solute in 1.0 liter of solution. **4.61** (**a**) 1.17 *M* $\mathrm{ZnCl_2}$ (**b**) 0.158 mol $\mathrm{H^+}$ (**c**) 58.3 mL of 6.00 *M* NaOH **4.63** 16 g $\mathrm{Na^+}(aq)$ **4.65** BAC of 0.08 = 0.02 *M* $\mathrm{CH_3CH_2OH}$ (alcohol) **4.67** (**a**) 316 g ethanol (**b**) 401 mL ethanol **4.69** (**a**) 0.15 *M* $\mathrm{K_2CrO_4}$ has the highest $\mathrm{K^+}$ concentration. (**b**) 30.0 mL of 0.15 *M* $\mathrm{K_2CrO_4}$ has more $\mathrm{K^+}$ ions. **4.71** (**a**) 0.25 *M* $\mathrm{Na^+}$, 0.25 *M* $\mathrm{NO_3^-}$ (**b**) 1.3×10^{-2} *M* $\mathrm{Mg^{2+}}$, 1.3×10^{-2} *M* $\mathrm{SO_4{}^{2-}}$ (**c**) 0.0150 *M* $\mathrm{C_6H_{12}O_6}$ (**d**) 0.111 *M* $\mathrm{Na^+}$, 0.111 *M* $\mathrm{Cl^-}$, 0.0292 *M* $\mathrm{NH_4{}^+}$, 0.0146 *M* $\mathrm{CO_3{}^{2-}}$ **4.73** (**a**) 16.9 mL 14.8 *M* $\mathrm{NH_3}$ (**b**) 0.296 *M* $\mathrm{NH_3}$ **4.75** (**a**) The ratio of drug molecules to cancer cells is 4.5×10^6 **4.77** 1.398 *M* $\mathrm{CH_3COOH}$ **4.79** (**a**) 20.0 mL of 0.15 *M* HCl (**b**) 0.224 g KCl (**c**) The KCl reagent is virtually free relative to the HCl solution. The KCl analysis is more cost-effective.

4.81 (**a**) 38.0 mL of 0.115 *M* $\mathrm{HClO_4}$ (**b**) 769 mL of 0.128 *M* HCl (**c**) 0.408 *M* $\mathrm{AgNO_3}$ (**d**) 0.275 g KOH **4.83** 27 g $\mathrm{NaHCO_3}$ **4.85** (**a**) Molar mass of metal hydroxide is 103 g/mol. (**d**) 0.927 g $\mathrm{Ni(OH)_2}$ (**e**) 0.0667 *M* $\mathrm{Ni^{2+}}(aq)$, 0.0667 *M* $\mathrm{K^+}(aq)$, 0.100 *M* $\mathrm{SO_4{}^{2-}}(aq)$ **4.89** 91.39% $\mathrm{Mg(OH)_2}$

4.91 (**a**) $\mathrm{U}(s) + 2\,\mathrm{ClF_3}(g) \longrightarrow \mathrm{UF_6}(g) + \mathrm{Cl_2}(g)$ (**b**) This is not a metathesis reaction. (**c**) It is a redox reaction.

4.95 (**a**) $\mathrm{Al(OH)_3}(s) + 3\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Al^{3+}}(aq) + 3\,\mathrm{H_2O}(l)$ (**b**) $\mathrm{Mg(OH)_2}(s) + 2\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Mg^{2+}}(aq) + 2\,\mathrm{H_2O}(l)$ (**c**) $\mathrm{MgCO_3}(s) + 2\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Mg^{2+}}(aq) + \mathrm{H_2O}(l) + \mathrm{CO_2}(g)$ (**d**) $\mathrm{NaAl(CO_3)(OH)_2}(s) + 4\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Na^+}(aq) + \mathrm{Al^{3+}}(aq) + 3\,\mathrm{H_2O}(l) + \mathrm{CO_2}(g)$ (**e**) $\mathrm{CaCO_3}(s) + 2\,\mathrm{H^+}(aq) \longrightarrow \mathrm{Ca^{2+}}(aq) + \mathrm{H_2O}(l) + \mathrm{CO_2}(g)$ [In (**c**), (**d**) and (**e**), one could also write the equation for formation of bicarbonate, e.g., $\mathrm{MgCO_3}(s) + \mathrm{H^+}(aq) \longrightarrow \mathrm{Mg^{2+}} + \mathrm{HCO_3{}^-}(aq)$.]

4.100 (**a**) 2.055 *M* $\mathrm{Sr(OH)_2}$ (**b**) $2\,\mathrm{HNO_3}(aq) + \mathrm{Sr(OH)_2}(aq) \longrightarrow \mathrm{Sr(NO_3)_2}(aq) + 2\,\mathrm{H_2O}(l)$ (**c**) 2.62 *M* $\mathrm{HNO_3}$

4.106 (**a**) $\mathrm{Mg(OH)_2}(s) + 2\,\mathrm{HNO_3}(aq) \longrightarrow \mathrm{Mg(NO_3)_2}(aq) + 2\,\mathrm{H_2O}(l)$ (**b**) $\mathrm{HNO_3}$ is the limiting reactant. (**c**) 0.130 mol $\mathrm{Mg(OH)_2}$, 0 mol $\mathrm{HNO_3}$, and 0.00250 mol $\mathrm{Mg(NO_3)_2}$ are present.

Chapter 5

5.1 (**a**) The food that the caterpillar eats. (**b**) As the caterpillar climbs, part of the food energy it uses is released as heat, so $q < 0$. (**c**) Yes, the caterpillar does work as it moves its mass up against the force of gravity. (**d**) Yes, the amount of work is determined by the specific way (path) that the caterpillar moves. (**e**) No, the change in potential energy depends only on the initial and final positions of the caterpillar. **5.4** (**a**) (iii) (**b**) none of them (**c**) all of them **5.6** (**a**) The sign of w is (+). (**b**) The sign of q is (−). (**c**) The sign of w is positive and the sign of q is negative, so we cannot absolutely determine the sign of ΔE. It is likely that the heat lost is much smaller than the work done on the system, so the sign of ΔE is probably positive. **5.9** (**a**) $\mathrm{N_2}(g) + \mathrm{O_2}(g) \longrightarrow 2\,\mathrm{NO}(g)$. Since $\Delta V = 0$, $w = 0$. (**b**) $\Delta H = \Delta H_f = 90.37$ kJ. The definition of a formation reaction is one where elements combine to form one mole of a single product. The enthalpy change for such a reaction is the enthalpy of formation. **5.12** Statements I and III are true.

5.13 (**a**) $E_{\mathrm{el}} = -4.3 \times 10^{-18}$ J (**b**) $\Delta E_{\mathrm{el}} = 4.1 \times 10^{-18}$ J (**c**) The electrostatic potential energy of the system increases (becomes less negative) as the separation between the oppositely charged particles increases. **5.15** (**a**) $F_{\mathrm{el}} = -2.3 \times 10^{-8}$ N (**b**) $F_g = 1.0 \times 10^{-47}$ N (**c**) The electrostatic force of attraction is 2.3×10^{39} times larger.

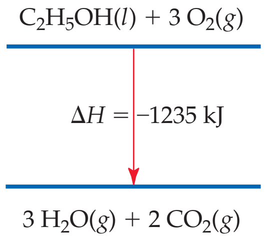
5.17 $w = 2.6 \times 10^{-18}$ J. **5.19** (**a**) Matter cannot leave or enter a closed system. (**b**) Neither matter nor energy can leave or enter an isolated system. (**c**) Any part of the universe not part of the system is called the surroundings. **5.21** (**a**) According to the first law of thermodynamics, energy is conserved. (**b**) The *internal energy* (**E**) of a system is the sum of all the kinetic and potential energies of the system components. (**c**) The internal energy of a closed system increases when work is done on the system and when heat is transferred to the system. **5.23** (**a**) $\Delta E = -0.077$ kJ, endothermic (**b**) $\Delta E = -22.1$ kJ, exothermic **5.25** (**a**) Since no work is done by the system in case (2), the gas will absorb most of the energy as heat; the case (2) gas will have the higher temperature. (**b**) In case (1) energy will be used to do work on the surroundings ($-w$), but some will be absorbed as heat ($+q$). In case (2) $w = 0$ and q is (+). (**c**) ΔE is greater for case (2) because the entire 100 J increases the internal energy of the system rather than a part of the energy doing work on the surroundings. **5.27** Your change in elevation and your change in gravitational potential energy are state functions. The other two quantities depend on the specific path taken. **5.29** (**a**) For Path 1, $q = +470$ J. (**b**) For Path 2, $w = +110$ J. **5.31** $w = -51$ J

5.33 Statements I and II are true. **5.35** (**a**) We must know either the temperature, T, or the values of P and ΔV in order to calculate ΔE from ΔH. (**b**) ΔE is larger than ΔH. (**c**) Because the value of Δn is negative, the quantity $(-P\Delta V)$ is positive. We add a positive quantity to ΔH to calculate ΔE, so ΔE must be larger.

5.37 $\Delta E = 1.47$ kJ; $\Delta H = 0.824$ kJ

5.39 (**a**) $\mathrm{C_2H_5OH}(l) + 3\mathrm{O_2}(g) \longrightarrow 3\,\mathrm{H_2O} + 2\,\mathrm{CO_2}(g)$, $\Delta H = -1235$ kJ

(**b**)

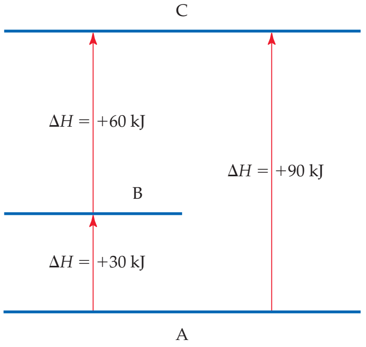


$\mathrm{C_2H_5OH}(l) + 3\,\mathrm{O_2}(g)$
$\Delta H = -1235$ kJ
$3\,\mathrm{H_2O}(g) + 2\,\mathrm{CO_2}(g)$

5.41 (**a**) $\Delta H = -142.3$ kJ/mol $\mathrm{O_3}(g)$ (**b**) $2\,\mathrm{O_3}(g)$ has the higher enthalpy. **5.43** (**a**) Exothermic (**b**) −87.9 kJ heat transferred (**c**) 15.7 g MgO produced (**d**) 602 kJ heat absorbed **5.45** (**a**) −29.5 kJ (**b**) −4.11 kJ (**c**) 60.6 J **5.47** (**a**) $\Delta H = +2248$ kJ (**b**) $\Delta H = -4496$ kJ (**c**) The exothermic forward reaction is more likely to be thermodynamically favored. (**d**) Vaporization is endothermic. If the product were $\mathrm{H_2O}(g)$, the reaction would have a less negative ΔH. **5.49** (**a**) J/mol-°C or J/mol − K (**b**) J/g-°C or J/g-K (**c**) To calculate heat capacity from specific heat, the mass of the particular piece of copper pipe must be known. **5.51** (**a**) 4.184 J/g-K (**b**) 75.40 J/mol-°C (**c**) 774 J/°C (**d**) 904 kJ **5.53** (**a**) 2.93×10^3 J (**b**) It will require more heat to increase the temperature of one mole of ethanol, $\mathrm{C_2H_5OH}(l)$, by a certain amount than to increase the temperature of one mole of water, $\mathrm{H_2O}(l)$, by the same amount. **5.55** (**a**) 5.31 kJ (**b**) −41.6 kJ/mol NaOH

5.57 (**a**) $\Delta H_{\mathrm{rxn}} = -25.5$ kJ/g $\mathrm{C_6H_4O_2}$ (**b**) -2.75×10^3 kJ/mol $\mathrm{C_6H_4O_2}$ **5.59** (**a**) Total heat capacity of the calorimeter = 8.74 kJ/°C (**b**) 30.0 kJ/g (**c**) If water is lost, the total heat capacity of the calorimeter will decrease. **5.61** (**a**) +90 kJ

(**b**)

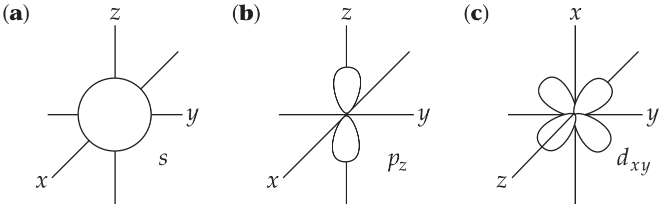


5.63 $\Delta H = -1300.0$ kJ **5.65** $\Delta H = -2.49 \times 10^3$ kJ **5.67** $\Delta H^\circ = +201.9$ kJ **5.69** (**a**) *Standard conditions* for enthalpy changes are $P = 1$ atm and some common temperature, usually 298 K. (**b**) *Enthalpy of formation* is the enthalpy change that occurs when a compound is formed from its component elements. (**c**) *Standard enthalpy of formation*, ΔH_f°, is the enthalpy change that accompanies formation of one mole of a substance from elements in their standard states.

5.71 (**a**) $N_2(g) + \frac{1}{2}O_2(g) \longrightarrow N_2O(g)$, $\Delta H_f^\circ = 81.6$ kJ
(**b**) $Fe(s) + \frac{3}{2}Cl_2(g) \longrightarrow FeCl_3(s)$, $\Delta H_f^\circ = -400$ kJ
(**c**) $P_4(s, \text{white}) + 5\,O_2(g) \longrightarrow P_4O_{10}(s)$, $\Delta H_f^\circ = -2940.1$ kJ
(**d**) $Ca(s) + H_2(g) + O_2(g) \longrightarrow Ca(OH)_2(s)$, $\Delta H_f^\circ = -986.2$ kJ
5.73 $\Delta H^\circ_{rxn} = -847.6$ kJ **5.75** (**a**) $\Delta H^\circ_{rxn} = -508.3$ kJ
(**b**) $\Delta H^\circ_{rxn} = +88.3$ kJ (**c**) $\Delta H^\circ_{rxn} = +246$ kJ (**d**) $\Delta H^\circ_{rxn} = -196.1$ kJ
5.77 $\Delta H_f^\circ = -248$ kJ
5.79 (**a**) $C_8H_{18}(l) + \frac{25}{2}O_2(g) \longrightarrow 8\,CO_2(g) + 9\,H_2O(g)$
(**b**) $\Delta H_f^\circ = -259.5$ kJ
5.81 (**a**) $C_2H_5OH(l) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 3\,H_2O(g)$
(**b**) $\Delta H^\circ_{rxn} = -1235$ kJ (**c**) 2.11×10^4 kJ/L heat produced (**d**) 0.071284 g CO_2/kJ heat emitted **5.83** Statements I and III are true. **5.85** (**a**) ΔH for the reaction is +1312 kJ. D(C—Cl) = 1312/4 = +328 kJ (**b**) The difference between the value calculated in part (**a**) and the value from Table **5.4** is zero, to three significant figures.
5.87 (**a**) $\Delta H = -103$ kJ (**b**) $\Delta H = -1295$ kJ **5.89** (**a**) ΔH for the reaction calculated using bond enthalpies is −485 kJ. (**b**) The estimate from part (**a**) is less negative or larger than the true reaction enthalpy. (**c**) ΔH for the reaction calculated using enthalpies of formation is −572 kJ. **5.91** (**a**) *Fuel value* is the amount of energy produced when 1 g of a substance (fuel) is combusted. (**b**) 5 g of fat (**c**) These products of metabolism are expelled as waste via the alimentary tract, $H_2O(l)$ primarily in urine and feces, and $CO_2(g)$ as gas when breathing. **5.93** (**a**) 108 or 1×10^2 Cal/serving (**b**) Sodium does not contribute to the calorie content of the food because it is not metabolized by the body. **5.95** 59.7 Cal
5.97 (**a**) $\Delta H_{comb} = -1850$ kJ/mol C_3H_4, −1926 kJ/mol C_3H_6, −2044 kJ/mol C_3H_8 (**b**) $\Delta H_{comb} = -4.616 \times 10^4$ kJ/kg C_3H_4, -4.578×10^4 kJ/kg C_3H_6, -4.635×10^4 kJ/kg C_3H_8 (**c**) These three substances yield nearly identical quantities of heat per unit mass, but propane is marginally higher than the other two. **5.99** 1.0×10^{12} kg $C_6H_{12}O_6$/yr **5.101** (**a**) $E_{el} = 1.8 \times 10^2$ J (**b**) If the spheres are released, they will move away from each other. (**c**) v = 19 m/s **5.103** The spontaneous air bag reaction is probably exothermic, with $-\Delta H$ and thus $-q$. When the bag inflates, work is done by the system, so the sign of w is also negative. **5.107** $\Delta H = 38.95$ kJ; $\Delta E = 36.48$ kJ **5.108** 1.8×10^4 bricks **5.112** (**a**) $\Delta H^\circ_{rxn} = -353.0$ kJ (**b**) 1.2 g Mg needed **5.115** $\Delta H = -445$ kJ **5.117** (**a**) $\Delta H^\circ = -633.2$ kJ (**b**) 3 mol of acetylene gas has greater enthalpy. (**c**) Fuel values are 50 kJ/g $C_2H_2(g)$, 42 kJ/g $C_6H_6(l)$. **5.119** (**a**) Enthalpies of combustion: For $C_4H_6(g)$, $\Delta H = -2543$ kJ/mol; for $C_4H_8(g)$, $\Delta H = -2719$ kJ/mol; for $C_4H_{10}(g)$, $\Delta H = -2878$ kJ/mol. (**b**) Fuel values: For $C_4H_6(g)$, fuel value = 47.0 kJ/g; for $C_4H_8(g)$, fuel value = 48.5 kJ/g; for $C_4H_{10}(g)$, fuel value = 49.5 kJ/g. (**c**) Percentage H by mass: For $C_4H_6(g)$, 11.2 % H; for $C_4H_8(g)$, 14.4% H; for $C_4H_{10}(g)$, 17.3% H. (**d**) The fuel value increases with increasing percentage of hydrogen by mass.

Chapter 6

6.2 (**a**) 0.1 m or 10 cm (**b**) No. Visible radiation has wavelengths much shorter than 0.1 m. (**c**) Energy and wavelength are inversely proportional. Photons of the longer 0.1-m radiation have less energy than visible photons. (**d**) Radiation with $\lambda = 0.1$ m is in the low-energy portion of the microwave region. The appliance is probably a microwave oven. **6.5** (**a**) Increase (**b**) decrease **6.9** (**a**) $l = 1$ (**b**) $3p_y$ (**c**) (iii) **6.13** (**a**) Meters (**b**) 1/second (**c**) meters/second **6.15** (**a**) True (**b**) False. Ultraviolet light has shorter wavelengths than visible light. (**c**) False. X-rays travel at the same speed as microwaves. (**d**) False. Electromagnetic radiation and sound waves travel at different speeds. **6.1**7 Wavelength of X-rays < ultraviolet < green light < red light < infrared < radio waves **6.19** (**a**) $3.0 \times 10^{13}\ s^{-1}$ (**b**) 5.45×10^{-7} m = 545 nm. (**c**) The radiation in (**b**) is visible; the radiation in (**a**) is not. (**d**) 1.50×10^4 m **6.21** $4.6 \times 10^{14}\ s^{-1}$; red. **6.23** (iii) **6.25** (**a**) 1.95×10^{-19} J (**b**) 4.81×10^{-19} J (**c**) 328 nm **6.27** (**a**) $\lambda = 3.3\ \mu m$, $E = 6.0 \times 10^{-20}$ J; $\lambda = 0.154$ nm, $E = 1.29 \times 10^{-15}$ J (**b**) The 3.3-μm photon is in the infrared region and the 0.154-nm photon is in the X-ray region; the X-ray photon has the greater energy. **6.29** (**a**) 6.11×10^{-19} J/photon (**b**) 368 kJ/mol (**c**) 1.64×10^{15} photons (**d**) 368 kJ/mol **6.31** (**a**) The ~1×10^{-6} m radiation is in the infrared portion of the spectrum. (**b**) 8.1×10^{16} photons/s **6.33** (**a**) $E_{min} = 7.22 \times 10^{-19}$ J (**b**) $\lambda = 275$ nm (**c**) $E_{120} = 1.66 \times 10^{-18}$ J. The excess energy of the 120-nm photon is converted into the kinetic energy of the emitted electron. $E_k = 9.3 \times 10^{-19}$ J/electron. **6.35** When an electron in a hydrogen atom transitions from $n = 1$ to $n = 3$, the atom “expands”.
6.37 (**a**) Emitted (**b**) absorbed (**c**) emitted **6.39** (**a**) $E_2 = -5.45 \times 10^{-19}$ J; $E_6 = -0.606 \times 10^{-19}$ J; $\Delta E = 4.84 \times 10^{-19}$ J; $\lambda = 410$ nm (**b**) visible, violet **6.41** (**a**) (ii) (**b**) $n_i = 3$, $n_f = 2$; $\lambda = 6.56 \times 10^{-7}$ m; this is the red line at 656 nm. $n_i = 4$, $n_f = 2$; $\lambda = 4.86 \times 10^{-7}$ m; this is the blue-green line at 486 nm. $n_i = 5$, $n_f = 2$; $\lambda = 4.34 \times 10^{-7}$ m; this is the blue-violet line at 434 nm. **6.43** (**a**) Ultraviolet region (**b**) $n_i = 7$, $n_f = 1$ **6.45** The order of increasing frequency of light absorbed is: $n = 4$ to $n = 9$; $n = 3$ to $n = 6$; $n = 2$ to $n = 3$; $n = 1$ to $n = 2$
6.47 (**a**) $\lambda = 5.6 \times 10^{-37}$ m (**b**) $\lambda = 2.65 \times 10^{-34}$ m (**c**) $\lambda = 2.3 \times 10^{-13}$ m (**d**) $\lambda = 1.51 \times 10^{-11}$ m **6.49** 3.16×10^3 m/s
6.51 (**a**) $\Delta x \geq 4 \times 10^{-27}$ m (**b**) $\Delta x \geq 3 \times 10^{-10}$ m **6.53** (**a**) False (**b**) false **6.55** (**a**) $n = 4$, $l = 3, 2, 1, 0$ (**b**) $l = 2$, $m_l = -2, -1, 0, 1, 2$ (**c**) $m_l = 2$, $l \geq 2$ or $l = 2, 3$ or 4 **6.57** (**a**) $3p$: $n = 3$, $l = 1$ (**b**) $2s$: $n = 2$, $l = 0$ (**c**) $4f$: $n = 4$, $l = 3$ (**d**) $5d$: $n = 5$, $l = 2$ **6.59** (**a**) 2, 1, 0, −1, −2 (**b**) $^1/_2$, $-^1/_2$ **6.61** (**a**) Impossible, $1p$ (**b**) possible (**c**) possible (**d**) impossible, $2d$ **6.63**



6.65 (**a**) The $4s$ orbital has three radial nodes. (**b**) Like all p orbitals, the $2p_x$ orbital has a single nodal plane. (**c**) The most probable distance of an electron from the nucleus in a $2s$ orbital is smaller than for an electron in a $3s$ orbital. (**d**) $1s < 2p < 3d < 4f < 6s$ **6.67** (**a**) For the He^+ ion, the $2s$ and $2p$ orbitals have the same energy. (**b**) Yes. In a helium atom, the $2s$ orbital is lower in energy than the $2p$ orbital.
6.69 (**a**) No. Both configurations follow the Pauli exclusion principle. (**b**) No. Both configurations follow Hund’s rule. (**c**) No. In the absence of a magnetic field, we cannot say which configuration has the lower energy. **6.71** (**a**) 6 (**b**) 10 (**c**) 2 (**d**) 14 **6.73** (**a**) “Valence electrons” are those involved in chemical bonding. They are part or all of the outer-shell electrons listed after the core. (**b**) “Core electrons” are inner-shell electrons that have the electron configuration of the nearest noble-gas element. (**c**) Each box represents an orbital. (**d**) Each half-arrow in an orbital diagram represents an electron. The direction of the half-arrow represents electron spin. **6.75** (**a**) Cs, $[Xe]6s^1$ (**b**) Ni, $[Ar]4s^23d^8$ (**c**) Se, $[Ar]4s^23d^{10}4p^4$ (**d**) Cd, $[Kr]5s^24d^{10}$ (**e**) U, $[Rn]5f^36d^17s^2$ (**f**) Pb, $[Xe]6s^24f^{14}5d^{10}6p^2$ **6.77** (**a**) Be, 0 unpaired electrons (**b**) O, 2 unpaired electrons (**c**) Cr, 6 unpaired electrons (**d**) Te, 2 unpaired electrons **6.79** (**a**) The fifth electron would fill the $2p$ subshell before the $3s$. (**b**) Either the core is [He], or the outer electron configuration should be $3s^23p^3$. (**c**) The $3p$ subshell would fill before the $3d$.
6.81 (**a**) $\lambda_A = 3.6 \times 10^{-8}$ m, $\lambda_B = 8.0 \times 10^{-8}$ m (**b**) $\nu_A = 8.4 \times 10^{15}\ s^{-1}$, $\nu_B = 3.7 \times 10^{15}\ s^{-1}$ (**c**) A, ultraviolet; B, ultraviolet **6.84** 35.0 min

6.86 1.6×10^{18} photons **6.91** (**a**) The Paschen series lies in the infrared. (**b**) $n_i = 4, \lambda = 1.87 \times 10^{-6}$ m; $n_i = 5, \lambda = 1.28 \times 10^{-6}$ m; $n_i = 6, \lambda = 1.09 \times 10^{-6}$ m **6.95** $\lambda = 10.6$ pm **6.97** (**a**) The nodal plane of the p_z orbital is the *xy*-plane. (**b**) The two nodal planes of the d_{xy} orbital are the ones where $x = 0$ and $y = 0$. These are the *yz*- and *xz*-planes. (**c**) The two nodal planes of the $d_{x^2-y^2}$ orbital are the ones that bisect the *x*- and *y*-axes and contain the *z*-axis. **6.100** (**a**) Br: $[Ar]4s^23d^{10}4p^5$, 1 unpaired electron (**b**) Ga: $[Ar]4s^23d^{10}4p^1$, 1 unpaired electron (**c**) Hf: $[Xe]6s^24f^{14}5d^2$, 2 unpaired electrons (**d**) Sb: $[Kr]5s^24d^{10}5p^3$, 3 unpaired electrons (**e**) Bi: $[Xe]6s^24f^{14}5d^{10}6p^3$, 3 unpaired electrons (**f**) Sg: $[Rn]7s^25f^{14}6d^4$, 4 unpaired electrons **6.103** (**a**) 1.7×10^{28} photons (**b**) 34 s

Chapter 7

7.2 The largest brown sphere is Br^-, the intermediate blue one is Br, and the smallest red one is F. **7.5** (**a**) The bonding atomic radius of A, r_A, is $d_1/2$; $r_x = d_2 - (d_1/2)$. (**b**) The length of the X—X bond is $2r_x$ or $2d_2 - d_1$. **7.8** (**a**) $X + 2F_2 \longrightarrow XF_4$ (**b**) If X were a metal, the compound would be ionic and the charge on X would be 4+. (**c**) If X is a nonmetal, it could be C, which is similar in size to F, and indeed carbon tetrafluoride is a known compound. **7.9** The *p*-block. **7.11** (**a**) Of the elements listed, only Fe was known before 1700. (**b**) The seven metals known in ancient times, Fe, Cu, Ag, Sn, Au, Hg, and Pb, are mostly near the bottom of the activity series, Table **4.5**. **7.13** For elements 1–18, H, Li, and Na have minimum values of Z_{eff}; Ne and Ar have maximum values. **7.15** (**a**) For both Na and K, $Z_{eff} = 1$. (**b**) For both Na and K, $Z_{eff} = 2.2$. (**c**) Slater's rules give values closer to the detailed calculations: Na, 2.51; K, 3.49. (**d**) Both approximations give the same value of Z_{eff} for Na and K; neither accounts for the gradual increase in Z_{eff} moving down a group. (**e**) Following the trend from detailed calculations, we predict a Z_{eff} value of approximately 4.5. **7.17** The $n = 3$ electrons in Kr experience a greater effective nuclear charge and thus have a greater probability of being closer to the nucleus. **7.19** The best answer is (**c**). **7.21** (**a**) 1.37 Å (**b**) The distance between W atoms will decrease. **7.23** From the sum of the atomic radii, As—I = 2.58 Å. This is very close to the experimental value of 2.55 Å. **7.25** (**a**) $Cs > K > Li$ (**b**) $Pb > Sn > Si$ (**c**) $N > O > F$ **7.27** (**a**) False (**b**) true (**c**) false **7.29** Ga^{3+}: none; Zr^{4+}: Kr; Mn^{7+}: Ar; I^-: Xe; Pb^{2+}: Hg **7.31** (**a**) Na^+ (**b**) F^-, $Z_{eff} = 7$; Na^+, $Z_{eff} = 9$ (**c**) $S = 4.15$; F^-, $Z_{eff} = 4.85$; Na^+, $Z_{eff} = 6.85$ (**d**) For isoelectronic ions, as nuclear charge (Z) increases, effective nuclear charge (Z_{eff}) increases and ionic radius decreases. **7.33** (**a**) $Cl < S < K$ (**b**) $K^+ < Cl^- < S^{2-}$ (**c**) The neutral K atom has the largest radius because the *n*-value of its outer electron is larger than the *n*-value of valence electrons in S and Cl. The K^+ ion is smallest because, in an isoelectronic series, the ion with the largest Z has the smallest ionic radius. **7.35** (**a**) True. O^{2-} is larger than O because the increase in electron repulsions that accompanies addition of an electron causes the electron cloud to expand. (**b**) False. S^{2-} is larger than O^{2-} because for particles with like charges, size increases going down a family. (**c**) True. S^{2-} is larger than K^+ because the two ions are isoelectronic and K^+ has the larger Z and Z_{eff}. (**d**) True. K^+ is larger than Ca^{2+} because the two ions are isoelectronic and Ca^{2+} has the larger Z and Z_{eff}. **7.37** (**a**) $1s^22s^22p^63s^23p^63d^7$, or $[Ar]3d^7$ (**b**) $[Kr]5s^24d^{10}$ (**c**) $1s^22s^22p^63s^23p^64s^23d^{10}4p^6$, which is [Kr], which is a noble-gas configuration (**d**) $[Kr]4d^{10}$ (**e**) $1s^22s^22p^63s^23p^6$, which is [Ar], a noble-gas configuration. **7.39** The correct answer is (e), more than one of the choices (both Ni^{2+} and Pt^{2+} are d^8 systems).

7.41 (**a**) Second electron affinity of Cl: $Cl^- + 1\,e^- \longrightarrow Cl^{2-}(g)$. (**b**) We predict that the second electron affinity of chlorine will be positive, since adding an electron to the chloride ion (a noble gas configuration) is not favorable. It is probably not possible to directly measure this quantity, because a positive value indicates that Cl^{2-} ion is unstable and will not form. **7.43** $Al(g) \longrightarrow Al^+(g) + 1e^-$; $Al^+(g) \longrightarrow Al^{2+}(g) + 1e^-$; $Al^{2+}(g) \longrightarrow Al^{3+}(g) + 1e^-$. The process for the first ionization energy requires the least amount of energy.

7.45 Of these three elements, Li has the highest second ionization energy. Both Li^+ and K^+ have the stable electron configurations of noble gases, but the unshielded 1*s* electron of Li^+ is much closer to the nucleus and requires more energy to remove.

7.47 (**a**) The larger the atom, the smaller its first ionization energy. (**b**) Of the nonradioactive elements, He has the largest first ionization energy. (**c**) Of the nonradioactive elements, Cs has the smallest first ionization energy. **7.49** (**a**) Cl (**b**) Ca (**c**) K (**d**) Ge (**e**) Sn **7.51** The electron affinity of K^+ is more negative. The electron-electron repulsions created by adding an electron to a neutral K atom causes the electron affinity of K to be greater (less negative) than that of K^+. **7.53** (**a**) Ionization energy (I_1) of Ne: $Ne(g) \longrightarrow Ne^+(g) + 1\,e^-$; $[He]2s^22p^6 \longrightarrow [He]2s^22p^5$; electron affinity ($E_1$) of F: $F(g) + 1\,e^- \longrightarrow F^-(g)$; $[He]2s^22p^5 \longrightarrow [He]2s^22p^6$. (**b**) I_1 of Ne is positive; E_1 of F is negative. (**c**) One process is apparently the reverse of the other, with one important difference. Ne has a greater Z and Z_{eff}, so we expect I_1 for Ne to be somewhat greater in magnitude and opposite in sign to E_1 for F. **7.55** (**a**) Decrease (**b**) Increase (**c**) The smaller the first ionization energy of an element, the greater the metallic character of that element. The trends in (**a**) and (**b**) are the opposite of the trends in ionization energy. **7.57** True. When forming ions, all metals form cations. The only nonmetallic element that forms cations is the metalloid Sb, which is likely to have significant metallic character. **7.59** Ionic: SnO_2, Al_2O_3, Li_2O, Fe_2O_3; molecular: CO_2, H_2O. Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. **7.61** MnO will react more readily with HCl.

7.63 (**a**) Dichlorine heptoxide (**b**) $2\,Cl_2(g) + 7\,O_2(g) \longrightarrow 2\,Cl_2O_7(l)$ (**c**) Cl_2O_7 is an acidic oxide, so it will be more reactive to base, OH^-. (**d**) The oxidation state of Cl in Cl_2O_7 is +7; the corresponding electron configuration for Cl is $[He]2s^22p^6$ or [Ne].

7.65 (**a**) $BaO(s) + H_2O(l) \longrightarrow Ba(OH)_2(aq)$
(**b**) $FeO(s) + 2\,HClO_4(aq) \longrightarrow Fe(ClO_4)_2(aq) + H_2O(l)$
(**c**) $SO_3(g) + H_2O(l) \longrightarrow H_2SO_4(aq)$
(**d**) $CO_2(g) + 2\,NaOH(aq) \longrightarrow Na_2CO_3(aq) + H_2O(l)$

7.67 $K > Ca > Mg$, based on the order of ionization energies.

7.69 (**a**) $2\,K(s) + Cl_2(g) \longrightarrow 2\,KCl(s)$
(**b**) $SrO(s) + H_2O(l) \longrightarrow Sr(OH)_2(aq)$
(**c**) $4\,Li(s) + O_2(g) \longrightarrow 2\,Li_2O(s)$ (**d**) $2\,Na(s) + S(l) \longrightarrow Na_2S(s)$

7.71 (**a**) The reactions of the alkali metals with hydrogen and with a halogen are redox reactions. Both hydrogen and the halogen gain electrons and are reduced. (The alkali metal loses electrons and is oxidized.) $Ca(s) + F_2(g) \longrightarrow CaF_2(s)$; $Ca(s) + H_2(g) \longrightarrow CaH_2(s)$. (**b**) The oxidation number of Ca in both products is +2. The electron configuration is that of Ar, $[Ne]3s^23p^6$. **7.73** (**a**) Br, $[Ar]4s^24p^5$; Cl, $[Ne]3s^23p^5$ (**b**) Br and Cl are in the same group, and both adopt a 1− ionic charge. (**c**) The question should have asked you to predict the relative first ionization energy. The ionization energy of Br is smaller than that of Cl, because the 4*p* valence electrons in Br are farther from to the nucleus and less tightly held than the 3*p* electrons of Cl. (**d**) Both react slowly with water to form HX + HOX. (**e**) The question should have asked you to predict the relative electron affinity. The electron affinity of Br is less negative than that of Cl, because the electron added to the 4*p* orbital in Br is farther from the nucleus and less tightly held than the electron added to the 3*p* orbital of Cl. (**f**) The question should have asked you to predict the relative atomic radius. The atomic radius of Br is larger than that of Cl, because the 4*p* valence electrons in Br are farther from the nucleus and less tightly held than the 3*p* electrons of Cl. **7.75** (**a**) The term *inert* was dropped because it no longer described all the Group 8A elements. (**b**) In the 1960s, scientists discovered that Xe would react with substances having a strong tendency to remove electrons, such as F_2. Thus, Xe could not be categorized as an "inert" gas. (**c**) The group is now called the noble gases. **7.77** (**a**) $2\,O_3(g) \longrightarrow 3\,O_2(g)$ (**b**) $Xe(g) + F_2(g) \longrightarrow XeF_2(g)$; $Xe(g) + 2\,F_2(g) \longrightarrow XeF_4(s)$; $Xe(g) + 3\,F_2(g) \longrightarrow XeF_6(s)$ (**c**) $S(s) + H_2(g) \longrightarrow H_2S(g)$ (**d**) $2\,F_2(g) + 2\,H_2O(l) \longrightarrow 4\,HF(aq) + O_2(g)$ **7.79** Up to $Z = 82$, there are three instances where atomic weights are reversed relative to atomic numbers: Ar and K; Co and Ni; Te and I. **7.81** (**a**) 5+ (**b**) 4.8+ (**c**) Shielding is greater for 3*p* electrons, owing to penetration by 3*s* electrons, so Z_{eff} for 3*p* electrons is less than that for 3*s* electrons. (**d**) The first electron lost is a 3*p* electron because it has a smaller Z_{eff} and experiences less attraction for the nucleus than a 3*s* electron does. **7.84** (**a**) The As—Cl distance is 2.24 Å. (**b**) The predicted As—Cl bond length is 2.21 Å **7.86** (**a**) Chalcogens, −2; halogens, −1. (**b**) The family with the larger value is: atomic radii, chalcogens; ionic radii of the most common oxidation state, chalcogens; first ionization energy, halogens; second ionization energy, halogens **7.89** *C*: $1s^22s^22p^2$. I_1 through I_4 represent loss of the 2*p* and 2*s* electrons in the outer shell of the atom. The values of $I_1 - I_4$ increase as expected. I_5 and I_6 represent loss of the 1*s* core electrons. These 1*s* electrons are much closer to the nucleus and experience the full nuclear charge, so the values of I_5 and I_6 are significantly greater than $I_1 - I_4$. **7.94** (**a**) Cl^-, K^+ (**b**) Mn^{2+}, Fe^{3+} (**c**) Sn^{2+}, Sb^{3+} **7.96** (**a**) For both H and the alkali metals, the added electron will complete an *ns* subshell, so shielding and repulsion effects will be similar. For the halogens, the electron is added to an *np* subshell, so the energy change is likely to be quite different. (**b**) True. The electron configuration of H is $1s^1$. The single 1*s* electron experiences no repulsion from other electrons and feels the full unshielded nuclear charge. The outer electrons of all other elements that form compounds are shielded by a spherical inner core of electrons and are less strongly attracted to the nucleus, resulting in larger bonding atomic radii. (**c**) Both H and the halogens have large ionization energies. The relatively large effective nuclear charge experienced by *np* electrons of the halogens is similar to the unshielded nuclear charge experienced by the H 1*s* electron. For the alkali metals, the *ns* electron being removed is effectively shielded by the core electrons, so ionization energies are low. (**d**) ionization energy of hydride, $H^-(g) \longrightarrow H(g) + 1e^-$ (**e**) electron affinity of hydrogen, $H(g) + 1\,e^- \longrightarrow H^-(g)$. The value for the ionization energy of hydride is equal in magnitude but opposite in sign to the electron affinity of hydrogen. **7.99** The most likely product is (**a**). **7.103** Electron configuration, $[Rn]7s^25f^{14}6d^{10}7p^5$; first ionization energy, 805 kJ/mol; electron affinity, −235 kJ/mol; atomic size, 1.65 Å; common oxidation state, −1. **7.106** (**a**) Li, $[He]2s^1$; $Z_{eff} \approx 1+$ (**b**) $I_1 \approx 5.45 \times 10^{-19}$ J/atom $\approx$ 328 kJ/mol (**c**) The estimated value of 328 kJ/mol is less than the Table **7.4** value of 520 kJ/mol. Our estimate for Z_{eff} was a lower limit; the [He] core electrons do not perfectly shield the 2*s* electron from the nuclear charge. (**d**) Based on the experimental ionization energy, $Z_{eff} = 1.26$. This value is greater than the estimate from part (**a**) but agrees well with the "Slater" value of 1.3 and is consistent with the explanation in part (**c**). **7.108** (**a**) Mg_3N_2 (**b**) $Mg_3N_2(s) + 3\,H_2O(l) \longrightarrow 3\,MgO(s) + 2\,NH_3(g)$; the driving force is the production of $NH_3(g)$. (**c**) 17% Mg_3N_2 (**d**) $3\,Mg(s) + 2\,NH_3(g) \longrightarrow Mg_3N_2(s) + 3\,H_2(g)$. NH_3 is the limiting reactant and 0.46 g H_2 is formed. (**e**) $\Delta H^\circ_{rxn} = -368.70$ kJ

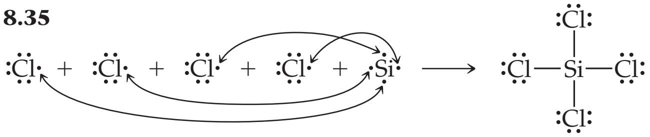
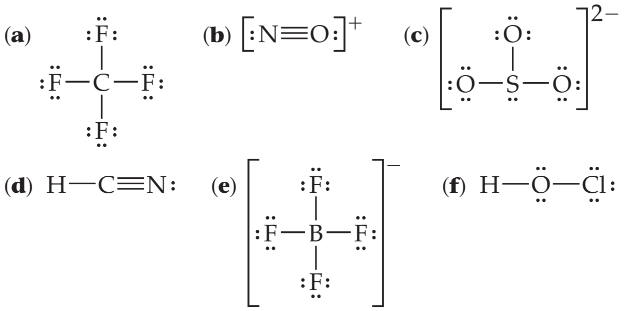
8.17 
(**b**) two (**c**) Mg loses electrons. **8.19** (**a**) AlF_3 (**b**) K_2S (**c**) Y_2O_3 (**d**) Mg_3N_2 **8.21** (**a**) Rb^+, $[Ar]4s^23d^{10}4p^6 = [Kr]$, noble-gas configuration (**b**) Rh^{3+}, $[Kr]4d^6$ (**c**) P^{3-}, $[Ne]3s^23p^6 = [Ar]$, noble-gas configuration (**d**) Sc^{3+}, $[Ne]3s^23p^6 = [Ar]$, noble-gas configuration (**e**) S^{2-}, $[Ne]3s^23p^6 = [Ar]$, noble-gas configuration (**f**) V^{2+}, $[Ar]3d^3$ **8.23** (**a**) Endothermic (**b**) $NaCl(s) \longrightarrow Na^+(g) + Cl^-(g)$ (**c**) Salts like NaCl, that have singly charged ions, will have smaller lattice energies compared with salts like CaO, that have doubly charged ions. **8.25** (**a**) Na^+, 1+; Ca^{2+}, 2+ (**b**) F^-, 1−; O^{2-}, 2− (**c**) CaO will have the larger lattice energy. (**d**) We expect the lattice energy of ScN to be slightly less than 8.10×10^3 kJ **8.27** (**a**) K—F, 2.71 Å; Na—Cl, 2.83 Å; Na—Br, 2.98 Å; Li—Cl, 2.57 Å (**b**) LiCl > KF > NaCl > NaBr (**c**) From Table **8.2**: LiCl, 1030 kJ; KF, 808 kJ; NaCl, 788 kJ; NaBr, 732 kJ. The predictions from ionic radii are correct. **8.29** Statement (**a**) is the best explanation. **8.31** The lattice energy of KI(*s*) is +649 kJ/mol. **8.33** (**a**) The bonding in (iii) and (iv) is likely to be covalent. (**b**) Covalent, because it is a gas at room temperature and below.

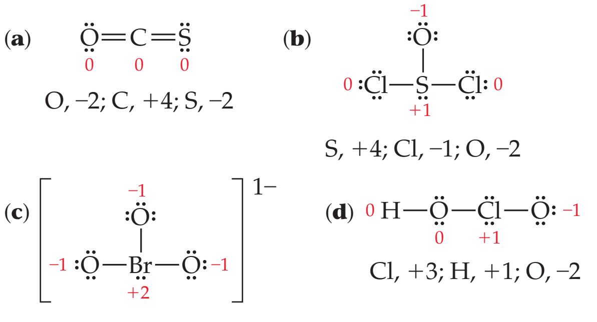
8.35



(**a**) 4 (**b**) 7 (**c**) 8 (**d**) 8 (**e**) 4 **8.37** (**a**) $:\ddot{O}=\ddot{O}:$ (**b**) four bonding electrons (two bonding electron pairs) (**c**) An O═O double bond is shorter than an O—O single bond. The greater the number of shared electron pairs between two atoms, the shorter the distance between the atoms. **8.39** Statements (ii) and (iii) are true. **8.41** (**a**) Mg (**b**) S (**c**) C (**d**) As **8.43** The bonds in (**a**), (**c**), and (**d**) are polar. The more electronegative element in each polar bond is (**a**) F (**c**) O (**d**) I. **8.45** (**a**) The calculated charge on H and Br is 0.12*e*. (**b**) Decrease **8.47** (**a**) SiF_4, molecular, silicon tetrachloride; LaF_3, ionic, lanthanum(III) fluoride (**b**) $FeCl_2$, ionic, iron(II) chloride; $ReCl_6$, molecular (metal in high oxidation state), rhenium hexachloride. (**c**) $PbCl_4$, molecular (by contrast to the distinctly ionic RbCl), lead tetrachloride; RbCl, ionic, rubidium chloride **8.49**



8.51 Statement (**b**) is most true. Keep in mind that when it is necessary to place more than an octet of electrons around an atom in order to minimize formal charge, there may not be a "best" Lewis structure. **8.53** Formal charges are shown on the Lewis structures; oxidation numbers are listed below each structure.



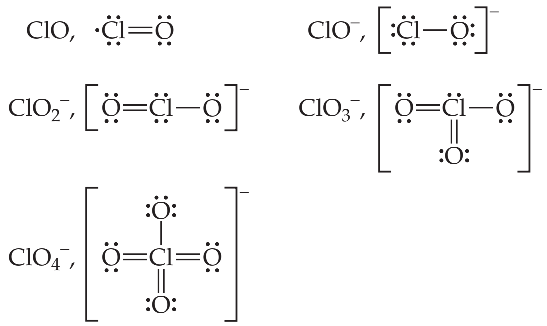
(**a**) O, −2; C, +4; S, −2

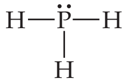
(**b**) S, +4; Cl, −1; O, −2

(**c**) Br, +5; O, −2

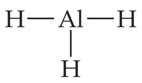
(**d**) Cl, +3; H, +1; O, −2

8.55 (**a**) $:\ddot{\underset{\cdot\cdot}{O}}-\underset{\cdot\cdot}{S}=\ddot{\underset{\cdot\cdot}{O}}$ (**b**) O_3 is isoelectronic with SO_2; both have 18 valence electrons. (**c**) Yes, there are multiple equivalent resonance structures for the molecule. (**d**) Because each S—O bond has partial double-bond character, the S—O bond length in SO_2 should be shorter than an S—O single bond but longer than an S—O double bond. **8.57** The more electron pairs shared by two atoms, the shorter the bond. Thus, the C—O bond lengths vary in the order $CO < CO_2 < CO_3^{2-}$. **8.59** Statements (i) and (iii) are true. **8.61** (**a**) AsF_5 is an exception to the octet rule. (**b**) BCl_3 is an exception to the octet rule. **8.63** Assume that the dominant structure is the one that minimizes formal charge. Following this guideline, only ClO^- obeys the octet rule. ClO, ClO_2^-, ClO_3^-, and ClO_4^- do not obey the octet rule.



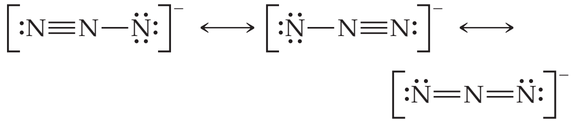
8.65 (**a**)


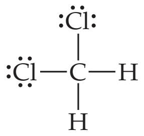
(**b**)



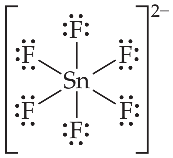
(**b**) Does not obey the octet rule. Central Al has only 6 electrons

(**c**)



(**d**)


(**e**)



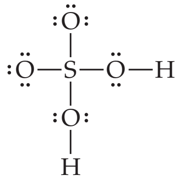
(**e**) Does not obey octet rule. Central Sn has 12 electrons.

8.67 (**a**)

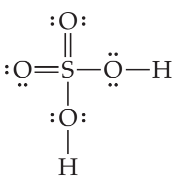
This structure violates the octet rule.

(**b**)

(**c**) Formal charges are minimized on the structure that violates the octet rule; this form is probably dominant.

8.69 (**a**)


(**b**)



8.71 (**a**) $\Delta H = -304$ kJ (**b**) $\Delta H = -82$ kJ (**c**) $\Delta H = -467$ kJ **8.73** Only statement (e) is true. **8.75** The Ca—O bond will be stronger than the Na—Cl bond, because the ion charges are greater. **8.77** A triple C—C bond **8.79** (**a**) No (**b**) bond 2 (**c**) bond 1 **8.87** (**a**) B—O. The most polar bond will be formed by the two elements with the greatest difference in electronegativity. (**b**) Te—I. These elements have the two largest covalent radii among this group. (**c**) TeI_2. The octet rule is satisfied for all three atoms. (**d**) P_2O_3. Each P atom needs to share 3 e^- and each O atom 2 e^- to achieve an octet. And B_2O_3. Although this is not a purely ionic compound, it can be understood in terms of gaining and losing electrons to achieve a noble-gas configuration. If each B atom were to lose 3 e^- and each O atom were to gain 2 e^-, charge balance and the octet rule would be satisfied. **8.88** (**a**) 0.162 *e* (**b**) the O atom

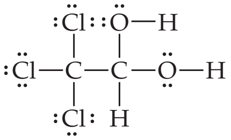
(**c**)
(**d**) 0

8.91

	Isomer A	Isomer B	Isomer C
Number of single bonds	5	6	5
Number of double bonds	2	0	2
Number of triple bonds	0	1	0
Number of nonbonding pairs	2	2	2

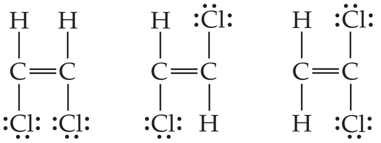
8.93 (**a**) +1 (**b**) −1 (**c**) +1 (assuming the odd electron is on N) (**d**) 0 (**e**) +3 **8.95** (**a**) The leftmost structure, with a N—N triple bond, leads to the most favorable formal charges. (**b**) The rightmost structure, with two double bonds, is most consistent with the observed bond lengths. **8.99** (**a**) $\Delta H = +40$ kJ/mol, ethanol has the lower enthalpy. (**b**) $\Delta H = -83$ kJ/mol, acetaldehyde has the lower enthalpy. (**c**) $\Delta H = +82$ kJ/mol, cyclopentene has the lower enthalpy. (**d**) $\Delta H = -55$ kJ/mol, acetonitrile has the lower enthalpy. **8.103** (**a**) $C_2H_3Cl_3O_2$ (**b**) $C_2H_3Cl_3O_2$

(**c**)

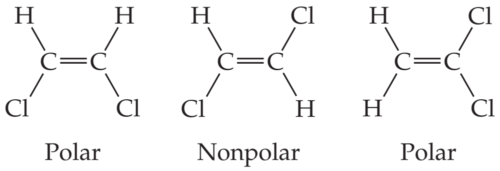


Chapter 9

9.1 Removing an atom from the equatorial plane of the trigonal bipyramid in Figure **9.3** creates a seesaw shape. **9.3** (**a**) Two electron-domain geometries, linear and trigonal bipyramidal (**b**) one electron-domain geometry, trigonal bipyramidal (**c**) one electron-domain geometry, octahedral (**d**) one electron domain geometry, octahedral (**e**) one electron domain geometry, octahedral (**f**) one electron-domain geometry, trigonal bipyramidal (This triangular pyramid is an unusual molecular geometry not listed in Table **9.3**. It could occur if the equatorial substituents on the trigonal bipyramid were extremely bulky, causing the nonbonding electron pair to occupy an axial position.) **9.5** (**a**) Zero. Moving from left to right along the x-axis of the plot, the distance between the Cl atoms increases. At very large separation, the potential energy of interaction approaches zero. (**b**) The Cl—Cl bond distance is approximately 2.0 Å. The Cl—Cl bond energy is approximately 240 kJ/mol. (**c**) Weaker. Under extreme pressure, the Cl—Cl bond gets shorter. The potential energy of the atom pair increases and the bond gets weaker. **9.11** (**a**) i, Two *s* atomic orbitals; ii, two *p* atomic orbitals overlapping end to end; iii, two *p* atomic orbitals overlapping side to side (**b**) i, σ-type MO; ii, σ-type MO; iii, π-type MO (**c**) i, antibonding; ii, bonding; iii, antibonding (**d**) i, the nodal plane is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. ii, there are two nodal planes; both are perpendicular to the interatomic axis. One is left of the left atom and the second is right of the right atom. iii, there are two nodal planes; one is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. The second contains the interatomic axis and is perpendicular to the first. **9.13** (**a**) The $2p_x$ orbital (**b**) Statements (i) and (iii) are true. **9.15** (**a**) Tetrahedral (**b**) bent (**c**) No, an AB_2 molecule with A=B double bonds would have a linear molecular geometry. **9.17** (**a**) Trigonal pyramidal (**b**) tetrahedral (**c**) one **9.19** (**a**) Octahedral (**b**) octahedral (**c**) square planar **9.21** (**a**) No effect on molecular shape (**b**) 1 nonbonding pair on P influences molecular shape (**c**) no effect (**d**) no effect (**e**) 1 nonbonding pair on S influences molecular shape **9.21** (**a**) 2 (**b**) 1 (**c**) none (**d**) 3 **9.23** (**a**) Tetrahedral, tetrahedral (**b**) trigonal bipyramidal, T-shaped (**c**) octahedral, square pyramidal (**d**) octahedral, square planar **9.25** (**a**) Linear, linear (**b**) tetrahedral, trigonal pyramidal (**c**) trigonal bipyramidal, seesaw (**d**) octahedral, octahedral (**e**) tetrahedral, tetrahedral (**f**) linear, linear **9.27** (**a**) i, trigonal planar; ii, tetrahedral; iii, trigonal bipyramidal (**b**) i, 0; ii, 1; iii, 2 (**c**) N and P (**d**) Cl (or Br or I). This T-shaped molecular geometry arises from a trigonal-bipyramidal electron-domain geometry with 2 nonbonding domains. Assuming each F atom has 3 nonbonding domains and forms only single bonds with A, A must have 7 valence electrons and be in or below the third row of the periodic table to produce these electron-domain and molecular geometries. **9.29** (**a**) 1, less than 109.5°; 2, less than 109.5° (**b**) 3, different than 109.5°; 4, less than 109.5° (**c**) 5, 180° (**d**) 6, slightly more than 120°; 7, less than 109.5°; 8, different than 109.5° **9.31** (**a**) NH_4^+ has zero nonbonding electron pairs on N and the largest bond angles. (**b**) NH_2^- has two nonbonding electron pairs on N and the smallest bond angles. **9.33** (**a**) PF_4^-, BrF_4^- and ClF_4^- (**b**) AlF_4^- (**c**) BrF_4^- (**d**) PF_4^- and ClF_4^+ **9.35** Statements (i) and (iii) are true. **9.37** (**a**) Yes. (**b**) Statement (iii) correctly describes the direction of the dipole moment. **9.39** (**a**) Nonpolar. The polar B—F bonds are arranged in a symmetrical trigonal planar geometry. (**b**) No. The added nonbonding electron pair requires that the electron domain geometry is tetrahedral and the shape is a trigonal pyramid. (**c**) Yes. In BF_2Cl, the bond dipoles do not cancel. **9.41** (**a**) IF (**d**) PCl_3 and (**f**) IF_5 are polar. **9.43** (**a**) Lewis structures



Molecular geometries



(**b**) The middle isomer has a zero net dipole moment. (**c**) C_2H_3Cl has only one isomer, and it has a dipole moment. **9.45** (**a**) True (**b**) false (**c**) false (**d**) true (**e**) true **9.47** (**a**) False (**b**) true (**c**) false (**d**) false **9.49** (**a**) B, $[He]2s^22p^1$ (**b**) F, $[He]2s^22p^5$ (**c**) sp^2 (**d**) A single 2*p* orbital is unhybridized. It lies perpendicular to the trigonal plane of the sp^2 hybrid orbitals. **9.51** (**a**) sp^2 (**b**) sp^3 (**c**) *sp* (**d**) sp^3 **9.53** Left, no hybrid orbitals discussed in this chapter form angles of 90° with each other; *p* atomic orbitals are perpendicular to each other; center, 109.5°, sp^3; right, 120°, sp^2 **9.55** (**a**) True (**b**) false (**c**) true (**d**) true

9.57

(a)

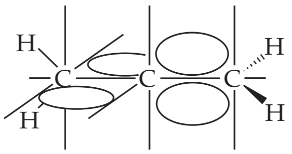
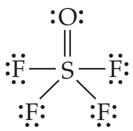
9.97



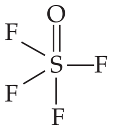
(**a**) *sp* hybridization (**b**) The molecule is nonplanar. (**c**) Allene has no dipole moment. (**d**) The bonding in allene would not be described as delocalized. The π electron clouds of the two adjacent C=C are mutually perpendicular, so there is no overlap and no delocalization of π electrons. **9.100** (**a**) All O atoms have sp^2 hybridization. (**b**) The two σ bonds are formed by overlap of sp^2 hybrid orbitals, the π bond is formed by overlap of atomic *p* orbitals, one nonbonded pair is in a *p* atomic orbital and the other five nonbonded pairs are in sp^2 hybrid orbitals. (**c**) unhybridized *p* atomic orbitals (**d**) four, two from the π bond and two from the nonbonded pair in the *p* atomic orbital **9.104** (**a**) σ antibonding (**b**) one (**c**) $\frac{1}{2}$ (**d**) answer (iv), longer and weaker **9.109** (**a**) The π_{2p} molecular orbital (**b**) the π_{2p}^* molecular orbital (**c**) The C—C bond is weaker in the excited state because an electron has been excited from a bonding MO to an antibonding MO. (**d**) Yes, the molecule would be easier to twist in the excited state because the π component of the C—C bond has been destroyed.

9.111 (**a**) $2\ SF_4(g) + O_2(g) \longrightarrow 2\ OSF_4(g)$

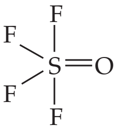
(**b**)



(**c**) $\Delta H = -551$ kJ, exothermic (**d**) The electron-domain geometry is trigonal bipyramidal. The O atom can be either equatorial or axial.



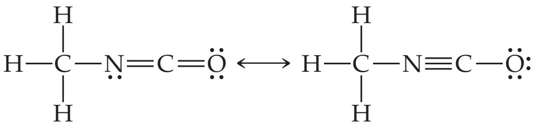
or



(**e**) In the structure on the left, there are 3 equatorial and 1 axial fluorine atoms. In the structure on the right, there are 2 equatorial and 2 axial fluorine atoms.

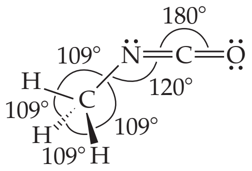
9.113

(**a**)



(The structure on the right does not minimize formal charges and will make a minor contribution to the true structure.)

(**b**)



Both resonance structures predict the same bond angles. (**c**) The two extreme Lewis structures predict different bond lengths. These bond length estimates assume that the structure minimizing formal charge makes a larger contribution to the true structure. C—O, 1.28 Å; C═N, 1.33 Å; C—N, 1.43 Å; C—H, 1.07 Å (**d**) The molecule will have a dipole moment. The C═N and C═O bond dipoles are opposite each other, but they are not equal. In addition, there are nonbonding electron pairs that are not directly opposite each other and will not cancel.

Chapter 10

10.1 It would be much easier to drink from a straw on Mars. When a straw is placed in a glass of liquid, the atmosphere exerts equal pressure inside and outside the straw. When we drink through a straw, we withdraw air, thereby reducing the pressure on the liquid inside. If only 0.007 atm is exerted on the liquid in the glass, a very small reduction in pressure inside the straw will cause the liquid to rise. **10.3** At the same temperature, volume and the lower pressure, the container would have half as many particles as at the higher pressure, so answer (**b**) is correct. **10.5** For a fixed amount of gas at constant pressure, the volume and temperature are proportional to each other. This is Charles' Law. Therefore, graph (**a**) is correct. **10.7** (**a**) $P_{\text{red}} < P_{\text{yellow}} < P_{\text{blue}}$ (**b**) $P_{\text{red}} = 0.28$ atm; $P_{\text{yellow}} = 0.42$ atm; $P_{\text{blue}} = 0.70$ atm **10.9** (**a**) Curve B is helium. (**b**) Curve B corresponds to the higher temperature. (**c**) The root mean square speed is highest. **10.11** The $NH_4Cl(s)$ ring will form at location a. **10.13** Statement (**c**) is false. Gaseous molecules are so far apart that there is no barrier to mixing, regardless of the identity of the molecules. **10.15** (**a**) 2.6×10^2 lb/in.^{2} (**b**) 1.8×10^3 kPa (**c**) 18 atm **10.17** (**a**) 8.20 m (**b**) 1.4 atm **10.19** (**a**) 0.349 atm (**b**) 265 mm Hg (**c**) 3.53×10^4 Pa (**d**) 0.353 bar (**e**) 5.13 psi **10.21** (**a**) $P = 773.4$ torr (**b**) $P = 1.018$ atm **10.23** (**i**) 0.31 atm (ii) 1.88 atm (iii) 0.136 atm **10.25** The action in (**c**) would double the pressure **10.27** (**a**) Boyle's Law, PV = constant or $P_1V_1 = P_2V_2$, at constant V, $P_1/P_2 = 1$; Charles' Law, V/T = constant or $V_1/T_1 = V_2/T_2$, at constant V, $T_1/T_2 = 1$; then $P_1/T_1 = P_2/T_2$ or P/T = constant. Amonton's law is that pressure and Kelvin temperature are directly proportional at constant volume. (**b**) 34.7 psi **10.29** (**a**) STP stands for standard temperature, 0 °C (or 273 K), and standard pressure, 1 atm. (**b**) 22.4 L (**c**) 24.5 L (**d**) 0.08315 L-bar/mol-K **10.31** Flask A contains the gas with a molar mass of 30 g/mol and flask B contains the gas with a molar mass of 60 g/mol.

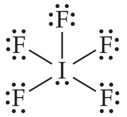
10.3 atm	585 mL	0.250 mol	295 K

10.35 8.2×10^2 kg He **10.37** (**a**) 5.5×10^{22} molecules (**b**) 6.5 kg air **10.39** (a) 91 atm (b) 2.3×10^2 L **10.41** $p = 4.9$ atm **10.43** (**a**) 29.8 g Cl_2 (**b**) 9.42 L (**c**) 501 K (**d**) 2.28 atm **10.45** (**a**) $n = 2 \times 10^{-4}$ mol O_2 (**b**) The roach needs 8×10^{-3} mol O_2 in 48 h, approximately 100% of the O_2 in the jar. **10.47** The density of a gas increases with increasing molar mass. The order of increasing density is : HF (20 g/mol) < CO (28 g/mol) < N_2O (44 g/mol) < Cl_2 (71 g/mol) **10.49** (**c**) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less than the air displaced by its volume. **10.51** (**a**) $d = 1.77$ g/L (**b**) molar mass = 80.1 g/mol **10.53** molar mass = 89.4 g/mol **10.55** 4.1×10^{-9} g Mg **10.57** (**a**) 21.4 L CO_2 (**b**) 40.7 L O_2 **10.59** 0.402 g Zn **10.61** (**a**) When the stopcock is opened, the volume occupied by $N_2(g)$ increases from 2.0 L to 5.0 L. $P_{N_2} = 0.40$ atm (**b**) When the gases mix, the volume of $O_2(g)$ increases from 3.0 L to 5.0 L. $P_{O_2} = 1.2$ atms (**c**) $P_t = 1.6$ atm **10.63** (**a**) $P_{\text{He}} = 1.87$ atm $P_{\text{Ne}} = 0.807$ atm, $P_{\text{Ar}} = 0.269$ atm, (**b**) $P_t = 2.95$ atm, **10.65** $X_{CO_2} = 0.000407$ **10.67** $P_{CO_2} = 0.305$ atm, $P_t = 1.232$ atm **10.69** $P_{CO_2} = 0.9$ atm **10.71** 2.5 mole % O_2 **10.73** $P_t = 2.47$ atm **10.75** (**a**) Decrease (**b**) increase (**c**) decrease **10.77** The root-mean-square speed of WF_6 is approximately 9 times slower than that of He. **10.79** (**a**) Average kinetic energy of the molecules increases. (**b**) Root mean square speed of the molecules increases. (**c**) Strength of an average impact with the container walls increases. (**d**) Total collisions of molecules with walls per second increases. **10.81** (**a**) In order of increasing speed and decreasing molar mass: HBr < NF_3 < SO_2 < CO < Ne (**b**) $u_{NF_3} = 324$ m/s (**c**) The most probable speed of an ozone molecule in the stratosphere is 306 m/s. **10.83** Statements (**a**) and (**d**) are true. **10.85** The order of increasing rate of effusion is ${}^{2}H^{37}Cl < {}^{1}H^{37}Cl < {}^{2}H^{35}Cl^{1} < H^{35}Cl$. **10.87** As_4S_6 **10.89** (**a**) Non-ideal-gas behavior is observed at very high pressures and low temperatures. (**b**) The real volumes of gas molecules and attractive intermolecular forces between molecules cause gases to behave nonideally. **10.91** Statement (**b**) is true. **10.93** From the value of b for Xe, the nonbonding radius is 2.72 Å. From Figure **7.7**, the bonding atomic radius of Xe is 1.40 Å. We expect the bonding radius of an atom to be smaller than its nonbonding radius, but our calculated value is nearly twice as large. **10.97** $P = 0.43$ mm Hg **10.100** (**a**) Molar mass of the unknown gas is 100.4 g/mol (**b**) We assume that the gases behave ideally, and that P, V and T are constant. **10.102** (**a**) 0.00378 mol O_2 (**b**) 0.0345 g C_8H_{18} **10.104** 42.2 g O_2 **10.106** $T_2 = 687$ °C **10.112** (**a**) 44.58% C, 6.596% H, 16.44% Cl, 32.38% N (**b**) $C_8H_{14}N_5Cl$ (**c**) Molar mass of the compound is required in order to determine molecular formula when the empirical formula is known. **10.114** (**a**) $NH_3(g)$ remains after reaction. (**b**) $P = 0.957$ atm (**c**) 7.33 g NH_4Cl **10.117** (**a**) $P_{IF_3} = 0.515$ atm (**b**) $X_{IF_5} = 0.544$

(**c**)



(**d**) Total mass in the flask is 20.00 g; mass is conserved.

Chapter 11

11.1 (**a**) The diagram best describes a liquid. (**b**) In the diagram, particles are close together, mostly touching, but there is no regular arrangement or order. This rules out a gaseous sample, where the particles are far apart, and a crystalline solid, which has a regular repeating structure in all three directions. **11.5** In its final state, methane is a gas at 185 °C. **11.8** (**a**) Propanol can engage in hydrogen bonding. (**b**) While both molecules are somewhat polar, we expect propanol to have a larger dipole moment because of its O—H bond. (**c**) Propanol boils at 97.2 °C, while ethyl methyl ether boils at 10.8 °C. The stronger intermolecular forces in propanol cause it to have the higher boiling point. **11.11** (**a**) Solid < liquid < gas (**b**) gas < liquid < solid (**c**) Matter in the gaseous state is most easily compressed because particles are far apart and there is much empty space. **11.13** (**a**) It increases. Kinetic energy is the energy of motion. As melting occurs, the motion of atoms relative to each other increases. (**b**) It increases somewhat. The density of liquid lead is less than the density of solid lead. The smaller density means a greater sample volume and greater average distance between atoms in three dimensions. **11.15** (**a**) The molar volumes of Cl_2 and NH_3 are nearly the same because they are both gases. (**b**) On cooling to 160 K, both compounds condense from the gas phase to the solid-state, so we expect a significant decrease in the molar volume. (**c**) The molar volumes are 0.0351 L/mol Cl_2 and 0.0203 L/mol NH_3 (**d**) Solid-state molar volumes are not as similar as those in the gaseous state, because most of the empty space is gone and molecular characteristics determine properties. $Cl_2(s)$ is heavier, has a longer bond distance and weaker intermolecular forces, so it has a significantly larger molar volume than $NH_3(s)$. (**e**) There is little empty space between molecules in the liquid state, so we expect their molar volumes to be closer to those in the solid state than those in the gaseous state. **11.17** (**a**) London dispersion forces (**b**) dipole–dipole forces (**c**) hydrogen bonding **11.19** (**a**) SO_2, dipole–dipole and London dispersion forces (**b**) CH_3COOH, London dispersion, dipole–dipole, and hydrogen bonding (**c**) H_2S, dipole–dipole and London dispersion forces (but not hydrogen bonding) **11.21** (**a**) In order of increasing polarizability: $CH_4 < SiH_4 < SiCl_4 < GeCl_4 < GeBr_4$ (**b**) The magnitudes of London dispersion forces and thus the boiling points of molecules increase as polarizability increases. The order of increasing boiling points is the order of increasing polarizability given in (**a**). **11.23** (**a**) H_2S (**b**) CO_2 (**c**) GeH_4 **11.25** Both rodlike butane molecules and spherical 2-methylpropane molecules experience dispersion forces. The larger contact surface between butane molecules facilitates stronger forces and produces a higher boiling point. **11.27** (**a**) A molecule must contain H atoms, bound to either N, O, or F atoms, in order to participate in hydrogen bonding with like molecules. (**b**) CH_3NH_2 and CH_3OH **11.29** (**a**) Replacing a hydroxyl hydrogen with a CH_3 group eliminates hydrogen bonding in that part of the molecule. This reduces the strength of intermolecular forces and leads to a lower boiling point. (**b**) $CH_3OCH_2CH_2OCH_3$ is a larger, more polarizable molecule with stronger London dispersion forces and thus a higher boiling point.

11.3

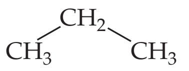
Physical Property	H_2O	H_2S
Normal boiling point, °C	100.00	−60.7
Normal melting point, °C	0.00	−85.5

(**a**) Based on its much higher normal melting point and boiling point, H_2O has much stronger intermolecular forces. (**b**) H_2O has hydrogen bonding, while H_2S has dipole–dipole forces. Both molecules have London dispersion forces. **11.33** SO_4^{2-} has a greater negative charge than BF_4^-, so ion–ion electrostatic attractions are greater in sulfate salts and they are less likely to form liquids. **11.35** (**a**) As temperature increases, surface tension decreases; they are inversely related. (**b**) As temperature increases, viscosity decreases; they are inversely related. (**c**) The same attractive forces that cause surface molecules to be difficult to separate (high surface tension) cause molecules elsewhere in the sample to resist movement relative to each other (high viscosity). **11.37** (**a**) Diagram (ii) shows stronger adhesive forces between the surface and the liquid. (**b**) Diagram (**i**) represents water on a nonpolar surface. (**c**) Diagram (ii) represents water on a polar surface. **11.39** (**a**) The three molecules have similar structures and experience the same types of intermolecular forces. As molar mass increases, the strength of dispersion forces increases and the boiling points, surface tension, and viscosities all increase. (**b**) Ethylene glycol has an —OH group at both ends of the molecule. This greatly increases the possibilities for hydrogen bonding; the overall intermolecular attractive forces are greater and the viscosity of ethylene glycol is much greater. (**c**) Water has the highest surface tension but lowest viscosity because it is the smallest molecule in the series. There is no hydrocarbon chain to inhibit their strong attraction to molecules in the interior of the drop, resulting in high surface tension. The absence of an alkyl chain also means the molecules can move around each other easily, resulting in the low viscosity. **11.41** (**a**) Melting, endothermic (**b**) evaporation, endothermic (**c**) deposition, exothermic (**d**) condensation, exothermic **11.43** (**a**) Melting, (s) $\longrightarrow$ (l) (**b**) endothermic (**c**) Heat of vaporization is usually larger than heat of fusion. **11.45** 2.3×10^3 g H_2O **11.47** (**a**) 39.3 kJ (**b**) 60 kJ **11.49** (**a**) False (**b**) true (**c**) false (**d**) true **11.51** Properties (**c**) intermolecular attractive forces, (**d**) temperature and (**e**) density of the liquid affect vapor pressure of a liquid. **11.53** (**a**) $CBr_4 < CHBr_3 < CH_2Br_2 < CH_2Cl_2 < CH_3Cl < CH_4$. (**b**) $CH_4 < CH_3Cl < CH_2Cl_2 < CH_2Br_2 < CHBr_3 < CBr_4$ (**c**) By analogy to attractive forces in HCl, the trend will be dominated by dispersion forces, even though four of the molecules are polar. The order of increasing boiling point is the order of increasing molar mass and increasing strength of dispersion forces. **11.55** (**a**) The temperature of the water in the two pans is the same. (**b**) Vapor pressure does not depend on either volume or surface area of the liquid. At the same temperature, the vapor pressures of water in the two containers are the same. **11.57** (**a**) Approximately 48 °C (**b**) approximately 340 torr (**c**) approximately 17 °C (**d**) approximately 1000 torr **11.59** (**a**) Yes, provided the temperature is less than the critical temperature. (**b**) No, at temperatures above the critical temperature a substance can only be a gas or a supercritical fluid. (**c**) No, at pressures below the triple point a substance can only be a solid or a gas. (**d**) It depends on the slope of the melting curve. For most substances the metling curve slopes to the right slightly, and in such cases the liquid cannot exist at temperatures below the triple point **11.61** (**a**) $H_2O(g)$ will condense to $H_2O(s)$ at approximately 4 torr; at a higher pressure, perhaps 5 atm or so, will melt to form $H_2O(l)$. (**b**) At 100 °C and

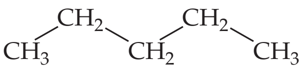
0.50 atm, water is in the vapor phase. As it cools, water vapor condenses to the liquid at approximately 82 °C, the temperature where the vapor pressure of liquid water is 0.50 atm. Further cooling results in freezing at approximately 0 °C. The freezing point of water increases with decreasing pressure, so at 0.50 atm the freezing temperature is very slightly above 0 °C. **11.63** (**a**) 24 K (**b**) Neon sublimes at pressures less than the triple point pressure, approximately 0.5 atm. (**c**) No **11.65** (**a**) Methane on the surface of Titan is likely to exist in both solid and liquid forms. (**b**) As pressure decreases upon moving away from the surface of Titan, $CH_4(l)$ (at −178 °C) will vaporize to $CH_4(g)$, and $CH_4(s)$ (at temperatures below −180 °C) will sublime to $CH_4(g)$. **11.67** In a nematic liquid crystalline phase, molecules are aligned along their long axes, but the molecular ends are not aligned. Molecules are free to translate in all dimensions, but they cannot tumble or rotate out of the molecular plane, or the order of the nematic phase is lost and the sample becomes an ordinary liquid. In an ordinary liquid, molecules are randomly oriented and free to move in any direction.

11.69 (**a**) True (**b**) false (**c**) true (**d**) false (**e**) false (**f**) true **11.71** (**a**) endothermic (**b**) decrease **11.73** nematic **11.75** (**a**) Decrease (**b**) increase (**c**) increase (**d**) increase (**e**) increase (**f**) increase (**g**) increase **11.78** (**a**) The *cis* isomer has stronger dipole-dipole forces; the *trans* isomer is nonpolar. (**b**) The *cis* isomer boils at 60.3 °C and the *trans* isomer boils at 47.5 °C. **11.80** (**a**) Four, all of them (**b**) three, benzene is nonpolar (**c**) one, phenol (**d**) Bromine is larger and more polarizable than chlorine, so the dispersion forces in bromobenzene are stronger than those in chlorobenzene and bromobenzene has the higher boiling point. (**e**) Phenol exhibits hydrogen bonding, which is the strongest intermolecular interaction among covalent molecules. **11.83** A plot of number of carbon atoms versus boiling point indicates that the boiling point of C_8H_{18} is approximately 130 °C. The more carbon atoms in the hydrocarbon, the longer the chain, the more polarizable the electron cloud, the higher the boiling point. **11.85** (**a**) Evaporation is an endothermic process. The heat required to vaporize sweat is absorbed from your body, helping to keep it cool. (**b**) The vacuum pump reduces the pressure of the atmosphere above the water until atmospheric pressure equals the vapor pressure of water and the water boils. Boiling is an endothermic process, and the temperature drops if the system is not able to absorb heat from the surroundings fast enough. As the temperature of the water decreases, the water freezes. **11.89** At low Antarctic temperatures, molecules in the liquid crystalline phase have less kinetic energy due to temperature, and the applied voltage may not be sufficient to overcome orienting forces among the ends of molecules. If some or all of the molecules do not rotate when the voltage is applied, the display will not function properly.

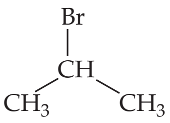
11.93



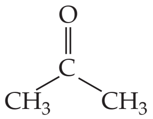
(i) M = 44



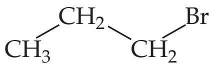
(ii) M = 72



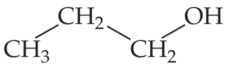
(iii) M = 123



(iv) M = 58



(v) M = 123



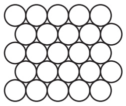
(vi) M = 60

(**a**) Molar mass: Compounds (**i**) and (ii) have similar rodlike structures. The longer chain in (ii) leads to greater molar mass, stronger London dispersion forces, and higher heat of vaporization. (**b**) Molecular shape: Compounds (iii) and (v) have the same chemical formula and molar mass but different molecular shapes. The more rodlike shape of (v) leads to more contact between molecules, stronger dispersion forces, and higher heat of vaporization. (**c**) Molecular polarity: Compound (iv) has a smaller molar mass than (ii) but a larger heat of vaporization, which must be due to the presence of dipole–dipole forces. (**d**) Hydrogen bonding interactions: Molecules (v) and (vi) have similar structures. Even though (v) has larger molar mass and dispersion forces, hydrogen bonding causes (vi) to have the higher heat of vaporization.

Chapter 12

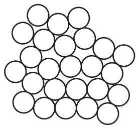
12.1 The red-orange compound is more likely to be a semiconductor and the white one an insulator. The red-orange compound absorbs light in the visible spectrum (red-orange is reflected, so blue-green is absorbed), while the white compound does not. This indicates that the red-orange compound has a lower energy electron transition than the white one. Semiconductors have lower energy electron transitions than insulators. **12.5** (**a**) The structure is hexagonal close-packed. (**b**) The coordination number, CN, is twelve. (**c**) CN(1) = 9, CN(2) = 6. **12.7** Fragment (**b**) is more likely to give rise to electrical conductivity. Fragment (**b**) has a delocalized π system, in which electrons are free to move. Mobile electrons are required for electrical conductivity. **12.9** We expect linear polymer (**a**), with ordered regions, to be more crystalline and to have a higher melting point than branched polymer (**b**). **12.11** Statement (**b**) is the best explanation. **12.13** (**a**) Hydrogen bonding, dipole-dipole forces, London dispersion forces (**b**) covalent chemical bonds (**c**) ionic bonds (**d**) metallic bonds **12.15** (**a**) Ionic (**b**) metallic (**c**) covalent-network (It could also be characterized as ionic with some covalent character to the bonds.) (**d**) molecular (**e**) molecular (**f**) molecular **12.17** Metallic, because of its melting point, conductivity, and insolubility in water

12.19 (**a**)



Crystalline

(**b**)



Amorphous

12.21

Two-dimensional structure	**(i)**	**(ii)**
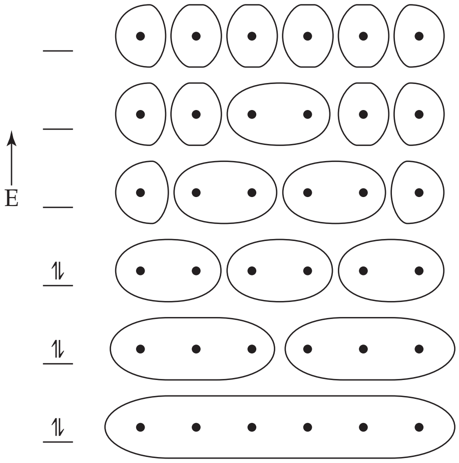
(**a**) unit cell		(**b**) γ, a, b	$\lambda = 90°, a = b$	$\lambda = 120°, a = b$
(**c**) lattice type	square	hexagonal

12.23 Tetragonal **12.25** (**e**) both triclinic and rhombohedral **12.27** (**b**) 2 **12.29** (**a**) Primitive hexagonal unit cell (**b**) NiAs **12.31** Potassium. A body-centered cubic structure has more empty space than a face-centered cubic one. The more empty space, the less dense the solid. We expect the element with the lowest density, potassium, to adopt the body-centered cubic structure. **12.33** (**a**) Structure types A and C have equally dense packing and are more densely packed than structure type B. (**b**) Structure type B is least densely packed. **12.35** (**a**) The radius of an Ir atom is 1.355 Å.

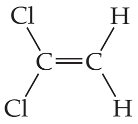
(**b**) The density of Ir is 22.67 g/cm^3 **12.37** (**a**) The radius of a Ca atom is 1.976 Å. (**b**) The density of Ca is 1.526 g/cm^3 **12.39** (**a**) 4 Al atoms per unit cell (**b**) coordination number = 12 (**c**) $a = 4.04$ Å or 4.04×10^{-8} cm (**d**) density = 2.71 g/cm^3 **12.41** Statement (**b**) is false. **12.43** (**a**) Interstitial alloy (**b**) substitutional alloy (**c**) intermetallic compound **12.45** (**a**) True (**b**) false (**c**) false **12.47** $Au_{2.8}Ag_{1.0}Cu_{1.1}$ **12.49** (**a**) True (**b**) false (**c**) false (**d**) false

12.51

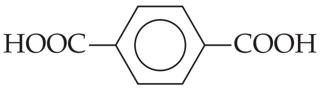


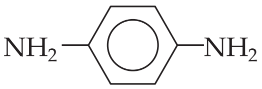
(**a**) Six AOs require six MOs (**b**) zero nodes in the lowest energy orbital (**c**) five nodes in highest energy orbital (**d**) two nodes in the HOMO (**e**) three nodes in the LUMO (**f**) The HOMO-LUMO energy gap for the six-atom diagram is smaller than the one for the four-atom diagram. In general, the more atoms in the chain, the smaller the HOMO-LUMO energy gap. **12.53** (**a**) Ag is more ductile. Mo has stronger metallic bonding, a stiffer lattice, and is less susceptible to distortion. (**b**) Zn is more ductile. Si is a covalent-network solid with a stiffer lattice than metallic Zn. **12.55** The order of increasing melting points is Y < Zr < Nb < Mo. Moving from Y to Mo, the number of valence electrons, occupancy of the bonding band, and strength of metallic bonding increase. Stronger metallic bonding requires more energy to break bonds and mobilize atoms, resulting in higher melting points. **12.57** (**a**) $SrTiO_3$ (**b**) Six (**c**) Each Sr atom is coordinated to a total of twelve O atoms in the eight unit cells that contain the Sr atom. **12.59** The density of MnS is 4.056 g/cm^3 **12.61** (**a**) 7.711 g/cm^3 (**b**) We expect Se^{2-} to have a larger ionic radius than S^{2-}, so HgSe will occupy a larger volume and the unit cell edge will be longer. (**c**) The density of HgSe is 8.241 g/cm^3. The greater mass of Se accounts for the greater density of HgSe. **12.63** (**a**) Cs^+ and I^- have the most similar radii and will adopt the CsCl-type structure. The radii of Na^+ and I^- are somewhat different; NaI will adopt the NaCl-type structure. The radii of Cu^+ and are very different; CuI has the ZnS-type structure. (**b**) CsI, 8; NaI, 6; CuI, 4 **12.65** (**a**) 6 (**b**) 3 (**c**) 6 **12.67** (**a**) False (**b**) true **12.69** (**a**) Ionic solids are much more likely to dissolve in water. (**b**) Covalent-network solids can become considerably better conductors of electricity via chemical substitution. **12.71** (**a**) CdS (**b**) GaN (**c**) GaAs **12.73** Si, (**d**) is the best choice; we want an element that has more valence electrons than Ga. **12.75** (**a**) A 1.1 eV photon corresponds to a wavelength of 1.1×10^{-6} m, or 1100 nm (**b**) According to the figure, Si can absorb all wavelengths in the visible portion of the solar spectrum. (**c**) Si absorbs wavelengths less than 1,100 nm. This corresponds to approximately 80–90% of the total area under the curve. **12.77** The emitted light has a wavelength of 713 nm. This is red light in the visible region of the electromagnetic spectrum. **12.79** The band gap is approximately 1.85 eV, which corresponds to a wavelength of 672 nm. **12.81** (**a**) A monomer is a small molecule with low molecular mass that can be joined with other monomers to form a polymer. They are the repeating units of a polymer. (**b**) ethene (also known as ethylene) **12.83** Reasonable values for a polymer's molecular weight are 10,000 amu, 100,000 amu, and 1,000,000 amu. **12.85** (**d**) shows the polyester repeat unit.

12.87



12.89





12.91 (**a**) Flexibility of the molecular chains causes flexibility of the bulk polymer. Flexibility is enhanced by molecular features that inhibit order, such as branching, and diminished by features that encourage order, such as cross-linking or delocalized π electron density. (**b**) Less flexible **12.93** Low degree of crystallinity **12.95** 1–100 nm. **12.97** (**a**) False. As particle size decreases, the band gap increases. (**b**) False. As particle size decreases, the band gap increases and hence wavelength of emitted light decreases. **12.99** 2.47×10^5 Au atoms **12.101** Statement (**b**) is correct. **12.109** The wavelength that corresponds to a photon with this energy is 564 nm. **12.111** (**a**) Zinc sulfide, ZnS (**b**) covalent (**c**) In the solid, each Si is bound to four C atoms in a tetrahedral arrangement, and each C is bound to four Si atoms in a tetrahedral arrangement, producing an extended three-dimensional network, much like diamond. SiC is high-melting because melting requires breaking covalent Si—C bonds, which takes a huge amount of thermal energy. It is hard because the three-dimensional lattice resists any deformation that would weaken the Si—C bonding network. **12.122** (**a**) 109° (**b**) 120° (**c**) atomic p orbitals **12.126** (**a**) 2.50×10^{22} Si atoms (To 1 sig fig, the result is 2×10^{22} Si atoms.) (**b**) 1.29×10^{-3} mg P (1.29 μg P) **12.128** 32 Si atoms

Chapter 13

13.1 (**a**) < (**b**) < (**c**) **13.3** (**a**) No (**b**) The ionic solid with the smaller lattice energy will be more soluble in water. **13.7** Vitamin B_6 is more water soluble. Vitamin E is more fat soluble. **13.9** (**a**) Yes, the *molarity* changes with a change in temperature. (**b**) No, *molality* does not change with change in temperature. **13.11** The volume inside the balloon will be 0.5 L, assuming perfect osmosis across the semipermeable membrane. **13.13** (**a**) False (**b**) false (**c**) true **13.15** (**a**) Dispersion (**b**) hydrogen bonding (**c**) ion–dipole (**d**) dipole–dipole **13.17** Very soluble (**b**) ΔH_{mix} will be the largest negative number. In order for ΔH_{soln} to be negative, the magnitude of ΔH_{mix} must be greater than the magnitude of $(\Delta H_{solute} + \Delta H_{solvent})$. **13.19** (**a**) ΔH_{solute} (**b**) ΔH_{mix} **13.21** (**a**) ΔH_{soln} is nearly zero. Since the solute and solvent experience very similar London dispersion forces, the energy required to separate them individually and the energy released when they are mixed are approximately equal. $\Delta H_{solute} + \Delta H_{solvent} \approx -\Delta H_{mix}$. (**b**) The entropy of the system increases when heptane and hexane form a solution. From part (**a**), the enthalpy of mixing is nearly zero, so the increase in entropy is the driving force for mixing in all proportions. **13.23** (**a**) Supersaturated (**b**) The bits of glass scraped from the vessel act as a seed crystal, a place where solute molecules can align to form a crystal. The excess chromium nitrate is crystallizing out. (**c**) 116 g crystals form **13.25** (**a**) Unsaturated (**b**) saturated (**c**) saturated (**d**) unsaturated **13.27** (**a**) We expect the liquids water and glycerol to be miscible in all proportions. (**b**) Hydrogen bonding, dipole-dipole forces, London dispersion forces **13.29** Toluene, $C_6H_5CH_3$, is the best solvent for nonpolar solutes. Without polar groups or nonbonding electron pairs, it forms only dispersion interactions with itself and other molecules. **13.31** (**a**) Carbon tetrachloride (**b**) water **13.33** (**a**) CCl_4 is more soluble because dispersion forces among nonpolar CCl_4 molecules are similar to dispersion forces in hexane. (**b**) C_6H_6 is a nonpolar hydrocarbon and will be more soluble in the similarly nonpolar hexane. (**c**) The long, rodlike hydrocarbon chain of octanoic acid forms strong dispersion interactions and causes it to be more soluble in hexane. **13.35** (**a**) False (**b**) true (**c**) false (**d**) true **13.37** $S_{He} = 5.6 \times 10^{-4}\,M$, $S_{N_2} = 9.0 \times 10^{-4}\,M$ **13.39** (**a**) 2.15% Na_2SO_4 by mass (**b**) 3.15 ppm Ag **13.41**(**a**) $X_{CH_3OH} = 0.0427$ (**b**) 7.35% CH_3OH by mass (**c**) 2.48 m CH_3OH **13.43** (**a**) $1.46 \times 10^{-2}\,M$ $Mg(NO_3)_2$ (**b**) 1.12 M $LiClO_4 \cdot 3H_2O$ (**c**) 0.350 M HNO_3 **13.45** (**a**) 4.70 m C_6H_6 (**b**) 0.235 m NaCl **13.47** (**a**) 43.01% H_2SO_4 by mass (**b**) $X_{H_2SO_4} = 0.122$ (**c**) 7.69 m H_2SO_4 (**d**) 5.827 M H_2SO_4 **13.49** (**a**) $X_{CH_3OH} = 0.227$ (**b**) 7.16 m CH_3OH (**c**) 4.58 M CH_3OH **13.51** (**a**) 0.150 mol $SrBr_2$ (**b**) 1.56×10^{-2} mol KCl (**c**) 4.44×10^{-2} mol $C_6H_{12}O_6$ **13.53** (**a**) Weigh out 1.3 g KBr, dissolve in water, dilute with stirring to 0.75 L. (**b**) Weigh out 2.62 g KBr, dissolve it in 122.38 g H_2O to make exactly 125 g of 0.180 m solution. **13.55** 71% HNO_3 by mass **13.57** (**a**) 3.82 m Zn (**b**) 26.8 M Zn **13.59** (**a**) Dissolve 244 g KBr in water, dilute with stirring to 1.85 L. (**b**) Dissolve 214 g $Pb(NO_3)_2$ in water, dilute with stirring to 1.20 L. **13.61** The minimum pressure required to initiate reverse osmosis is greater than 5.1 atm. **13.63** (**a**) False (**b**) true (**c**) true (**d**) false **13.65** The vapor pressure of both solutions is 17.5 torr. Because these two solutions are so dilute, they have essentially the same vapor pressure. Generally, the less concentrated solution, the one with fewer moles of solute per kilogram of solvent, will have the higher vapor pressure. **13.67** (**a**) $P_{H_2O} = 186.4$ torr (**b**) 78.9 g $C_3H_8O_2$ **13.69** (**a**) $X_{Eth} = 0.2812$ (**b**) $P_{soln} = 238$ torr (**c**) X_{Eth} in vapor $= 0.472$ **13.71** (**a**) 106.3 °C (**b**) $i = 1.6$ **13.73** 0.050 m LiBr $<$ 0.120 m glucose $<$ 0.050 m $Zn(NO_3)_2$ **13.75** (**a**) $T_f = -115.0\,°C$, $T_b = 78.7\,°C$ (**b**) $T_f = -67.3\,°C$, $T_b = 64.2\,°C$ (**c**) $T_f = -0.4\,°C$, $T_b = 100.1\,°C$ (**d**) $T_f = -0.6\,°C$, $T_b = 100.2\,°C$ **13.77** 167 g $C_2H_6O_2$ **13.79** $\Pi = 0.0168$ atm $= 12.7$ torr **13.81** The approximate molar mass of adrenaline is 1.8×10^2 g. **13.83** Molar mass of lysozyme $= 1.39 \times 10^4$ g **13.85** $i = 2.8$ **13.87** (**a**) emulsion (**b**) sol (**c**) solid foam **13.89** Choice (**d**), $CH_3(CH_2)_{11}COONa$, is the best emulsifying agent. The long hydrocarbon chain will interact with the hydrophobic component, while the ionic end will interact with the hydrophilic component, as well as stabilize the colloid. **13.91** (**a**) No. The hydrophobic or hydrophilic nature of the protein will determine which electrolyte at which concentration will be the most effective precipitating agent. (**b**) Stronger. If a protein has been "salted out", protein-protein interactions are stronger than protein-solvent interactions and solid protein forms. (**c**) The first hypothesis seems plausible, since ion-dipole interactions among electrolytes and water molecules are stronger than dipole-dipole and hydrogen bonding interactions between water and protein molecules. But, we also know that ions adsorb on the surface of a hydrophobic colloid; the second hypothesis also seems plausible. If we could measure the charge and adsorbed water content of protein molecules as a function of salt concentration, then we could distinguish between these two hypotheses. **13.93** (**a**) Hydrochloride (**b**) free base (**c**) 0.492 M free base (**d**) 7.36 M hydrochloride (**e**) 275 mL of 12.0 M HCl **13.96** (**a**) $k_{Rn} = 7.27 \times 10^{-3}$ mol/L-atm (**b**) $P_{Rn} = 1.1 \times 10^{-4}$ atm; $S_{Rn} = 8.1 \times 10^{-7}\,M$ **13.101** (**a**) 2.69 m LiBr (**b**) $X_{LiBr} = 0.0994$ (**c**) 81.1% LiBr by mass **13.102** $X_{H_2O} = 0.808$; 0.0273 mol ions; 0.0137 mol NaCl; 0.798 g NaCl **13.105** (**a**) −0.6 °C (**b**) −0.4 °C **13.108** (**a**), CF_4, $1.7 \times 10^{-4}\,m$; $CClF_3$, $9 \times 10^{-4}\,m$; CCl_2F_2, $2.3 \times 10^{-2}\,m$; $CHClF_2$, $3.5 \times 10^{-2}\,m$ (**b**) dipole moment (**c**) 3.9×10^{-4} mol O_2

Chapter 14

14.1 The rate of the combustion reaction in the cylinder depends on the surface area of the droplets in the spray. The smaller the droplets, the greater the surface area exposed to oxygen, the faster the combustion reaction. In the case of a clogged injector, larger droplets lead to slower combustion. Uneven combustion in the various cylinders can cause the engine to run roughly and decrease fuel economy. **14.3** Equation (iv) (**b**) rate $= -\Delta[B]/\Delta t = ½\Delta[A]/\Delta t$ **14.9** (1) Total potential energy of the reactants (2) E_a, activation energy of the reaction (3) ΔE, net energy change for the reaction (4) total potential energy of the products **14.12** (**a**) $NO_2 + F_2 \longrightarrow NO_2F + F$; $NO_2 + F \longrightarrow NO_2F$ (**b**) $2NO_2 + F_2 \longrightarrow 2NO_2F$ (**c**) F (atomic fluorine) is the intermediate (**d**) rate $= k[NO_2][F_2]$ **14.15** (**a**) Net reaction: $AB + AC \longrightarrow BA_2 + C$ (**b**) A is the intermediate. (**c**) A_2 is the catalyst. **14.17** (**a**) *Reaction rate* is the change in the amount of products or reactants in a given amount of time. (**b**) Rates depend on concentration of reactants, surface area of reactants, temperature, and activation energy/presence of catalyst. (**c**) No. The stoichiometry of the reaction (mole ratios of reactants and products) must be known to relate rate of disappearance of reactants to rate of appearance of products.

14.19

Time (min)	Mol A	(a) Mol B	[A] (mol/L)	Δ[A] (mol/L)	(b) Rate (M/s)
0	0.065	0.000	0.65		
10	0.051	0.014	0.51	−0.14	2.3×10^{-4}
20	0.042	0.023	0.42	−0.09	1.5×10^{-4}
30	0.036	0.029	0.36	−0.06	1.0×10^{-4}
40	0.031	0.034	0.31	−0.05	0.8×10^{-4}

(**c**) $\Delta[B]_{avg}/\Delta t = 1.3 \times 10^{-4}\,M/s$

14.21

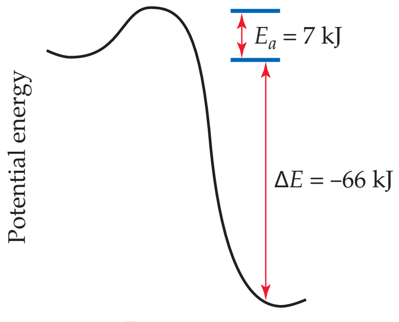
(**a**)

Time (s)	Time Interval (s)	Concentration (M)	ΔM	Rate (M/s)
0		0.0165		
2,000	2,000	0.0110	−0.0055	28×10^{-7}
5,000	3,000	0.00591	−0.0051	17×10^{-7}
8,000	3,000	0.00314	−0.00277	9.3×10^{-7}
12,000	4,000	0.00137	−0.00177	4.43×10^{-7}
15,000	3,000	0.00074	−0.00063	2.1×10^{-7}

(**b**) The average rate of reaction is $1.05 \times 10^{-6}\,M/s$ (**c**) The average rate between $t = 2000$ and $t = 12{,}000$ s ($9.63 \times 10^{-7}\,M/s$) is greater than the average rate between $t = 8{,}000$ and $t = 15{,}000$ s ($3.43 \times 10^{-7}\,M/s$). (**d**) From the slopes of the tangents to the graph, the rates are $12 \times 10^{-7}\,M/s$ at 5000 s, $5.8 \times 10^{-7}\,M/s$ at 8000 s. **14.23** (**a**) $-\Delta[H_2O_2]/\Delta t = \Delta[H_2]/\Delta t = \Delta[O_2]/\Delta t$ (**b**) $-\dfrac{1}{2}\Delta[N_2O]/\Delta t = \tfrac{1}{2}\Delta N_2/\Delta t = \Delta[O_2]/\Delta t$ (**c**) $-\Delta[N_2]/\Delta t = -1/3\Delta[H_2]/\Delta t = -1/2\Delta[H_2][NH_3]/\Delta t$ (**d**) $-\Delta[C_2H_5NH_2]/\Delta t = \Delta[C_2H_4]//\Delta t = \Delta[NH_3]/\Delta t$ **14.25** (**a**) $-\Delta[O_2]/\Delta t = 0.24$ mol/s; $\Delta[H_2O]/\Delta t = 0.48$ mol/s (**b**) P_{total} decreases by 28 torr/min. **14.27** (**a**) If [A] doubles, there is no change in the rate or the rate constant. (**b**) The reaction is zero order in A, second order in B, and second order overall. (**c**) units of $k = M^{-1}s^{-1}$ **14.29** (**a**) Rate $= k[N_2O_5]$ (**b**) Rate $= 1.16 \times 10^{-4}\,M/s$ (**c**) When the concentration of N_2O_5 doubles, the rate doubles. (**d**) When the concentration of N_2O_5 is halved, the rate is halved.

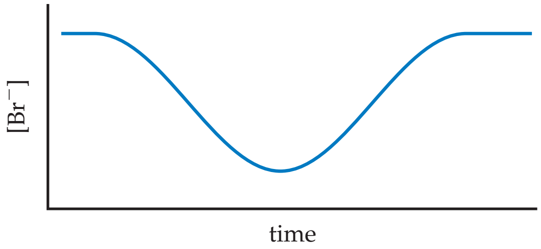
14.31 (a, b) $k = 1.7 \times 10^2\ M^{-1}s^{-1}$ (**c**) If $[OH^-]$ is tripled, the rate triples. (**d**) If $[OH^-]$ and $[CH_3Br]$ both triple, the rate increases by a factor of 9. **14.33** (**a**) Rate $= k[OCl^-][I^-]$ (**b**) $k = 60\ M^{-1}s^{-1}$. (**c**) Rate $= 6.0 \times 10^{-5}\ M/s$ **14.35** (**a**) Rate $= k[BF_3][NH_3]$ (**b**) The reaction is second order overall. (**c**) $k_{avg} = 3.41\ M^{-1}s^{-1}$ (**d**) 0.170 M/s **14.37** (**a**) Rate $= k[NO]^2[Br_2]$ (**b**) $k_{avg} = 1.2 \times 10^4\ M^{-2}s^{-1}$ (**c**) $\frac{1}{2}\Delta[NOBr]/\Delta t = -\Delta[Br_2]/\Delta t$ (**d**) $-\Delta[Br_2]/\Delta t = 8.4\ M/s$ **14.39** (**a**) A graph of ln[A] versus time yields a straight line for a first-order reaction. (**b**) On a graph of ln[A] versus time, the rate constant is the (–slope) of the straight line. **14.41**(**a**) $k = 3.0 \times 10^{-6}\ s^{-1}$ (**b**) $t_{1/2} = 3.2 \times 10^4$ s **14.43** (**a**) $p = 30$ torr (**b**) $t = 51$ s **14.45** Plot (In $P_{SO_2C1_2}$) versus time, $k = -\text{slope} = 2.19 \times 10^{-5}\ s^{-1}$ **14.47** (**a**) The plot of $1/[A]$ versus time is linear, so the reaction is second order in [A]. (**b**) $k = 0.040 M^{-1}\ min^{-1}$ (**c**) $t_{1/2} = 38$ min **14.49** (**a**) The plot of $1/[NO_2]$ versus time is linear, so the reaction is second order in NO_2. (**b**) $k = \text{slope} = 10\ M^{-1}s^{-1}$ (**c**) rate at 0.200 M = 0.400 M/s, rate at 0.100 M = 0.100 M/s rate at 0.050 M = 0.025 M/s **14.51** (**a**) The energy of the collision and the orientation of the molecules when they collide determine whether a reaction will occur. (**b**) The rate constant usually increases with an increase in reaction temperature. (**c**) The fraction of molecules with energy greater than the activation energy changes most dramatically with temperature. Frequency of collision and the orientation factor are lumped into the frequency factor, A, which is considered to be constant with temperature. **14.53** $f = 4.94 \times 10^{-2}$ At 400 K, approximately 1 out of 20 molecules has this kinetic energy.

14.55 (**a**)



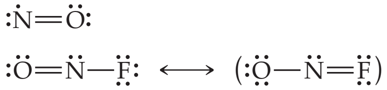
(**b**) E_a(reverse) = 73 kJ **14.57** (**a**) False (**b**) false (**c**) true **14.59** The order of slowest reaction to fastest reaction is: rate (**c**) < rate (**a**) < rate (**b**). **14.61** (**a**) $k = 1.1\ s^{-1}$ (**b**) $k = 13\ s^{-1}$ (**c**) The method in parts (**a**) and (**b**) assumes that the collision model and thus the Arrhenius equation describe the kinetics of the reactions. That is, activation energy is constant over the temperature range under consideration. **14.63** A plot of ln k versus $1/T$ has a slope of -5.64×10^3; $E_a = -R(\text{slope}) = 47.5$ kJ/mol **14.65** (**a**) An *elementary reaction* is a process that occurs as a single event; the order is given by the coefficients in the balanced equation for the reaction. (**b**) A *unimolecular* elementary reaction involves only one reactant molecule; a *bimolecular* elementary reaction involves two reactant molecules. (**c**) A *reaction mechanism* is a series of elementary reactions that describes how an overall reaction occurs and explains the experimentally determined rate law. (**d**) A *rate-determining step* is the slow step in a reaction mechanism. It limits the overall reaction rate. **14.67** (**a**) Unimolecular, rate $= k[Cl_2]$ (**b**) bimolecular, rate $= k[OCl^{-1}][H_2O]$ (**c**) bimolecular, rate $= k[NO][Cl_2]$ **14.69** (**a**) Two intermediates, B and C. (**b**) three transition states (**c**) C ⟶ D is fastest. (**d**) ΔE is positive. **14.71** (**a**) $H_2(g) + 2\,ICl(g) \longrightarrow I_2(g) + 2\,HCl(g)$ (**b**) HI is the intermediate. (**c**) If the first step is slow, the observed rate law is rate $= k[H_2][ICl]$. **14.73** (**a**) The two-step mechanism is consistent with the data, assuming that the second step is rate determining. (**b**) No. The linear plot guarantees that the overall rate law will include $[NO]^2$. Since the data were obtained at constant $[Cl_2]$, we have no information about reaction order with respect to $[Cl_2]$. **14.75** (**a**) A catalyst is a substance that changes (usually increases) the speed of a chemical reaction without undergoing a permanent chemical change itself. (**b**) A homogeneous catalyst is in the same phase as the reactants, while a hetereogeneous catalyst is in a different phase. (**c**) A catalyst has no effect on the overall enthalpy change for a reaction, but it does affect activation energy. It can also affect the frequency factor.

14.77



14.79 (**a**) Multiply the coefficients in the first reaction by 2 and sum. (**b**) $NO_2(g)$ is a catalyst. (**c**) $NO(g)$ is an intermediate. (**d**) This is an example of homogeneous catalysis. **14.81** (**a**) Use of chemically stable supports makes it possible to obtain very large surface areas per unit mass of the precious metal catalyst because the metal can be deposited in a very thin, even monomolecular, layer on the surface of the support. (**b**) The greater the surface area of the catalyst, the more reaction sites, the greater the rate of the catalyzed reaction. **14.83** To put two D atoms on a single carbon, it is necessary that one of the already existing C—H bonds in ethylene be broken while the molecule is adsorbed, so that the H atom moves off as an adsorbed atom and is replaced by a D atom. This requires a larger activation energy than simply adsorbing C_2H_4 and adding one D atom to each carbon. **14.85** Carbonic anhydrase lowers the activation energy of the reaction by 42 kJ. **14.87** (**a**) The catalyzed reaction is approximately 10,000,000 times faster at 25 °C (**b**) The catalyzed reaction is 180,000 times faster at 125 °C. **14.91** (**a**) Rate $= 4.7 \times 10^{-5}\ M/s$ (b, c) $k = 0.84\ M^{-2}s^{-1}$ (**d**) If the [NO] is increased by a factor of 1.8, the rate would increase by a factor of 3.2. **14.95** (**a**) The reaction is second order in NO_2. (**b**) If $[NO_2]_0 = 0.100\ M$ and $[NO_2]_t = 0.025\ M$, use the integrated form of the second-order rate equation to solve for t. $t = 48$ s **14.99** (**a**) The half-life of ^{241}Am is 4.3×10^2 yr, that of ^{125}I is 63 days (**b**) ^{125}I decays at a much faster rate. (**c**) 0.13 mg of each isotope remains after 3 half-lives. (**d**) The amount of ^{241}Am remaining after 4 days is 1.00 mg. The amount of ^{125}I remaining after 4 days is 0.96 mg. **14.103** (**a**) The plot of $1/[C_5H_6]$ versus time is linear and the reaction is second order. (**b**) $k = 0.167\ M^{-1}\ s^{-1}$ **14.107** (**a**) When the two elementary reactions are added, $N_2O_2(g)$ appears on both sides and cancels, resulting in the overall reaction. $2\,NO(g) + H_2(g) \longrightarrow N_2O(g) + H_2O(g)$ (**b**) First reaction, $-[NO]\Delta t = k[NO]^2$, second reaction, $-[H_2]/\Delta t = k[H_2]N_2O_2$ (**c**) N_2O_2 is the intermediate. (**d**) Because $[H_2]$ appears in the rate law, the second step must be slow relative to the first. **14.110** (**a**) $Cl_2(g) + CHCl_3(g) \longrightarrow HCl(g) + CCl_4(g)$ (**b**) $Cl(g)$, $CCl_3(g)$ (**c**) reaction 1, unimolecular; reaction 2, bimolecular; reaction 3, bimolecular (**d**) Reaction 2 is rate determining. (**e**) Rate $= k[CHCl_3][Cl_2]^{1/2}$. **14.115** The enzyme must lower the activation energy by 22 kJ in order to make it useful. **14.120** (**a**) $k = 8 \times 10^7\ M^{-1}\ s^{-1}$

(**b**)

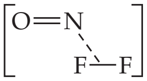


$$:\dot{N}{=}\ddot{O}:$$

$$:\ddot{O}{=}\ddot{N}{-}\ddot{\underset{..}{F}}: \longleftrightarrow (:\underset{..}{\ddot{O}}{-}\ddot{N}{=}\underset{..}{\ddot{F}})$$

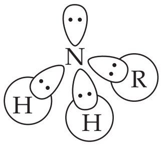
(**c**) NOF is bent with a bond angle of approximately 120°

(**d**)



(**e**) The electron-deficient NO molecule is attracted to electron-rich F_2 so the driving force for formation of the transition state is greater than simple random collisions.

14.123 (**a**)



(**b**) A reactant that is attracted to the lone pair of electrons on nitrogen will produce a tetrahedral intermediate. This can be a moiety with a full, partial, or even transient positive charge.

Chapter 15

15.1 (**a**) $k_f > k_r$ (**b**) The equilibrium constant is greater than one. **15.3** K is greater than one. **15.5** $A(g) + B(g) \rightleftharpoons AB(g)$ has the larger equilibrium constant. **15.6** From the smallest to the largest equilibrium constant, (c) < (b) < (a). **15.7** Statements (**a**) and (**c**) are true. **15.8** Statement (**b**) is true. **15.11** (**a**) The value of K_p at 500 K is less than the value of K_p at 300 K. (**b**) K_c decreases as T increases, so the reaction is exothermic. **15.13** (**a**) $K = 8.1 \times 10^{-3}$. (**b**) At equilibrium, the partial pressure of A is greater than the partial pressure of B. **15.15** (**a**) $K_c = [N_2O][NO_2]/[NO]^3$; homogeneous (**b**) $K_c = [CS_2][H_2]^4/[CH_4][H_2S]^2$; homogeneous (**c**) $K_c = [CO]^4/[Ni(CO)_4]$; heterogeneous (**d**) $K_c = [H^+][F^-]/[HF]$; homogeneous (**e**) $K_c = [Ag^+]^2/[Zn^{2+}]$; heterogeneous (**f**) $K_c = [H^+][OH^-]$; homogeneous (**g**) $K_c = [H_2O]^2[O_2]/[H_2O_2]^2$; heterogeneous **15.17** (**a**) Mostly reactants (**b**) mostly products **15.19** (**a**) True (**b**) true (**c**) false **15.21** $K_p = 1.0 \times 10^{-3}$ **15.23** (**a**) The equilibrium favors NO and Br_2 at this temperature. (**b**) $K_c = 77$ (**c**) $K_c = 8.8$ **15.25** (**a**) $K_p = 0.541$ (**b**) $K_p = 3.42$ (**c**) $K_c = 281$ **15.27** $K_c = 0.14$ **15.29** (**a**) $K_p = P_{O_2}$ (**b**) $K_c = [Hg(solv)^4][O_2(solv)]$ **15.31** $K_c = 10.5$ **15.33** (**a**) $K_p = 51$ (**b**) $K_c = 2.1 \times 10^3$ **15.35** (**a**) $[H_2] = 0.012\ M$, $[N_2] = 0.019\ M$, $[H_2O] = 0.138\ M$ (**b**) $K_c = 653.7 = 7 \times 10^2$ **15.37** (**a**) $P_{CO_2} = 4.10$ atm, $P_{H_2} = 2.05$ atm, $P_{H_2O} = 3.28$ atm, (**b**) $P_{CO_2} = 3.87$ atm, $P_{H_2} = 1.82$ atm, $P_{CO} = 0.23$ atm (**c**) $K_p = 0.11$ (**d**) $K_c = 0.11$ **15.39** $K_c = 2.0 \times 10^4$ **15.41** (**a**) True (**b**) true (**c**) false **15.43** (**a**) $Q = 1.1 \times 10^{-8}$, the reaction will proceed to the left. (**b**) $Q = 5.5 \times 10^{-12}$, the reaction will proceed to the right. (**c**) $Q = 2.19 \times 10^{-10}$, the mixture is at equilibrium. **15.45** $P_{Cl_2} = 5.0$ atm **15.47** $[Br_2] = 0.00767M$, $Br = 0.00282\ M$, 0.0451 g $Br(g)$ **15.49** $[I] = 2.10 \times 10^{-5}\ M$, $[I_2] = 1.43 \times 10^{-5}\ M$, 0.0362 g I_2 **15.51** (**a**) $[NH_3] = [H_2S] = 0.011\ M$ (**b**) 0.56 g **15.53** $[Ca^{2+}] = [CrO_4^{2-}] = 0.027\ M$ **15.55** $[NO] = \ = 0.002\ M$, $[N_2] = [O_2] = 0.087\ M$ **15.57** $[Br_2] = 0.020\ M$, $[Cl_2] = 0.12\ M$, $[BrCl] = 0.13\ M$ **15.59** (**a**) $P_{CH_3I} = P_{HI} = 0.422$ torr, $P_{CH_4} = 104.7$ torr, $P_{I_{12}} = 7.54$ torr **15.61** (**a**) Shift equilibrium to the right (**b**) decrease the value of K (**c**) shift equilibrium to the left (**d**) no effect (**e**) no effect (**f**) shift equilibrium to the right **15.63** (**a**) No effect (**b**) no effect (**c**) no effect (**d**) increase equilibrium constant (**e**) no effect **15.65** (**a**) Δn does not equal zero, so a change in volume at constant temperature will affect the fraction of products in the equilibrium mixture. (**b**) $\Delta H° = -155.7$ kJ (**c**) The reaction is exothermic, so the equilibrium constant will decrease with increasing temperature. **15.67** An increase in pressure by decreasing the volume favors formation of ozone. **15.69** (**a**) Endothermic (**b**) The equilibrium constant increases. (**c**) The forward rate constant increases by a larger amount than the reverse rate constant. **15.73** $K_p = 24.7$; $K_c = 3.67 \times 10^{-3}$ **15.76** (**a**) $P_{Br_2} = 0.161$ atm $P_{NO} = 0.628$ atm, $P_{NOBr} = 0.179$ atm; $K_c = 0.0643$ (**b**) $P_t = 0.968$ atm, (**c**) 10.49 g NOBr **15.79** At equilibrium, $P_{IBr} = 0.021$ atm, $P_{I_2} = P_{Br_2} = 1.9 \times 10^{-3}$ atm **15.82** $K_p = 4.33$, $K_c = 0.0480$ **15.86** $[CO_2] = [H_2] = 0.264\ M$, $[CO] = [H_2O] = 0.236\ M$ **15.89** (**a**) The fraction of CCl_4 that is converted to C and Cl_2 is 0.26 (26%). (**b**) At equilibrium, $P_{CCl_4} = 1.47$ atm and $P_{Cl_2} = 1.06$ atm. **15.91** Following the addition of 0.200 mol of HI, the equilibrium partial pressures are $P_{H_2} = P_{I_2} = 1.61$ atm and $P_{HI} = 11.2$ atm. **15.94** At equilibrium, $[H_4IO_6^-] = 0.0015\ M$

Chapter 16

16.1 (**a**) HCl, the H^+ donor, is the Brønsted–Lowry acid. NH_3, the H^+ acceptor, is the Brønsted–Lowry base. (**b**) HCl, the electron pair acceptor, is the Lewis acid. NH_3, the electron pair donor, is the Lewis base. **16.6** (**a**) HY is a strong acid. There are no neutral HY molecules in solution, only H^+ cations and Y^- anions. (**b**) HX has the smallest K_a value. It has most neutral acid molecules and fewest ions. (**c**) HX has fewest H^+ and highest pH. **16.12** (**a**) Molecule (**b**) is more acidic because its conjugate base is resonance-stabilized and the ionization equilibrium favors the more stable products. (**b**) Increasing the electronegativity of X increases the strength of both acids. As X becomes more electronegative and attracts more electron density, the O—H bond becomes weaker, more polar, and more likely to be ionized. An electronegative X group also stabilizes the anionic conjugate bases by delocalizing the negative charge. The equilibria favor products and the values of K_a increase. **16.13** HCl is the Brønsted–Lowry acid; NH_3 is the Brønsted–Lowry base. **16.15** (**a**) CH_3COOH (**b**) H_2O (**c**) $CH_3NH_3^+$ **16.17** (**a**) Acid, $Fe(ClO_4)_3$ or Fe^{3+}, base, H_2O (**b**) Acid, H_2O; base, CN^- (**c**) Acid, BF_3; base, $(CH_3)_3N$ (**d**) Acid, HIO; base, NH_2^- **16.19** (**a**) (**i**) IO_3^- (ii) NH_3 (**b**) (**i**) OH^- (ii) H_3PO_4

16.21

Acid	**+**	**Base**	$\rightleftharpoons$	**Conjugate Acid**	**+**	**Conjugate Base**

16.43 (**a**) Acidic (**b**) The range of possible integer pH values for the solution is 4-6. (**c**) Methyl red would help determine the pH of the solution more precisely. **16.45** (**a**) True (**b**) true (**c**) false

16.47 (**a**) $[H^+] = 8.5 \times 10^{-3}\,M$, pH $= 2.07$

(**b**) $[H^+] = 0.0419\,M$, pH $= 1.377$

(**c**) $[H^+] = 0.0250\,M$, pH $= 1.602$

(**d**) $[H^+] = 0.167\,M$, pH $= 0.778$

16.49 (**a**) $[OH^-] = 3.0 \times 10^{-3}\,M$, pH $= 11.48$

(**b**) $[OH^-] = 0.3758\,M$, pH $= 13.5750$

(**c**) $[OH^-] = 8.75 \times 10^{-5}\,M$, pH $= 9.942$

(**d**) $[OH^-] = 0.17\,M$, pH $= 13.23$

16.47 $3.2 \times 10^{-3}\,M$ NaOH

16.53 (**a**) $HBrO_2(aq) \rightleftharpoons H^+(aq) + BrO_2^-(aq)$,

$K_a = [H^+][BrO_2^-]/[HBrO_2]$;

$HBrO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + BrO_2^-(aq)$

$K_a = [H_3O^+][BrO_2^-]/[HBrO_2]$

(**b**) $C_2H_5COOH(aq) \rightleftharpoons H^+(aq) + C_2H_5COO^-(aq)$

$K_a = [H^+][C_2H_5COO^-]/[C_2H_5COOH]$;

$C_2H_5COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_2H_5COO^-(aq)$

$K_a = [H_3O^+][C_2H_5COO^-]/[C_2H_5COOH]$

16.55 $K_a = 1.4 \times 10^{-4}$ **16.57** $[H^+] = [ClCH_2COO^-] = 0.0110\,M$, $[ClCH_2COOH] = 0.089\,M$, $K_a = 1.4 \times 10^{-3}$

16.59 $0.089\,M$ CH_3COOH

16.61 $[H^+] = [C_6H_5COO^-] = 1.8 \times 10^{-3}\,M$, $[C_6H_5COOH] = 0.048\,M$

16.63 (**a**) $[H^+] = 1.1 \times 10^{-3}\,M$, pH $= 2.95$

(**b**) $[H^+] = 1.7 \times 10^{-4}\,M$, pH $= 3.76$

(**c**) $[OH^-] = 1.4 \times 10^{-5}\,M$, pH $= 9.15$

16.65 $[H^+] = 2.0 \times 10^{-2}\,M$, pH $= 1.71$

16.67 (**a**) $[H^+] = 2.8 \times 10^{-3}\,M$, 0.69% ionization

(**b**) $[H^+] = 1.4 \times 10^{-3}\,M$, 1.4% ionization

(**c**) $[H^+] = 8.7 \times 10^{-4}\,M$, 2.2% ionization

16.69 (**a**) $[H^+] = 5.1 \times 10^{-3}\,M$, pH $= 2.30$. (**b**) Yes. We started the calculation by assuming that only the first step made a significant contribution to $[H^+]$ and pH. Calculation proved this assumption to be true. Next we assumed $[H^+]$ from the first ionization was small relative to $0.040\,M$ citric acid; this assumption was not valid. Finally we assumed that additional ionization of $[H_2C_6H_5O_7^{2-}]$ was small, which was true. (**c**) $[C_6H_5O_7^{3-}]$ is much less than $[H^+]$.

16.71 (**a**) $HONH_3^+$ (**b**) When hydroxylamine acts as a base, the nitrogen atom accepts a proton. (**c**) In hydroxylamine, O and N are the atoms with nonbonding electron pairs; in the neutral molecule both have zero formal charges. Nitrogen is less electronegative than oxygen and more likely to share a lone pair of electrons with an incoming (and electron-deficient) H^+. The resulting cation with the +1 formal charge on N is more stable than the one with the +1 formal charge on O.

16.73 (**a**) $(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) + OH^-(aq)$;

$K_b = [(CH_3)_2NH_2^+][OH^-]/[(CH_3)_2NH]$

(**b**) $CO_3^{2-}(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$;

$K_b = [HCO_3^-][OH^-]/[(CH_3)_2NH]$

(**c**) $HCOO^-(aq) + H_2O(l) \rightleftharpoons HCOOH(aq) + OH^-(aq)$;

$K_b = [HCOOH][OH^-]/[HCOO^-]$

16.75 From the quadratic formula**,** $[OH^-] = 6.6 \times 10^{-3}\,M$, pH $= 11.82$. **16.77** (**a**) $[C_{10}H_{15}ON] = 0.033\,M$, $[C_{10}H_{15}ONH^+] = [OH^+] = 2.1 \times 10^{-3}\,M$ (**b**) $K_b = 1.4 \times 10^{-4}$

16.79 (**a**) $C_6H_5OH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_6H_5O^-(aq)$

(**b**) $K_b = 7.7 \times 10^{-5}$ (**c**) Phenol is a stronger acid than water.

16.81 (**a**) Acetic acid is stronger. (b) Hypochlorite ion is the stronger base**.** (**c**) For CH_3COO^-, $K_b = 5.6 \times 10^{-10}$; for ClO^-, $K_b = 3.3 \times 10^{-7}$.

16.83 (**a**) $[OH^-] = 6.3 \times 10^{-4}\,M$, pH $= 10.80$

(**b**) $[OH^-] = 9.2 \times 10^{-5}\,M$, pH $= 9.96$

(**c**) $[OH^-] = 3.3 \times 10^{-6}\,M$, pH $= 8.52$

16.85 $4.5\,M$ $NaCH_3COO$ **16.87** (**a**) Acidic (**b**) acidic (**c**) basic (**d**) neutral (**e**) acidic **16.89** (**a**) Cu^{2+}, higher cation charge (**b**) Fe^{3+}, higher cation charge (**c**) Al^{3+}, smaller cation radius, same charge

16.91 K_b for the anion of the unknown salt is 1.4×10^{-11}; K_b for F^- is 1.5×10^{-11}; The unknown salt is NaF. **16.93** (**a**) HNO_3 is a stronger acid than HNO_2 (**b**) H_2S is a stronger acid than H_2O. (**c**) H_2SO_4 is a stronger acid than H_2SeO_4. (**d**) CCl_3COOH is stronger than CH_3COOH **16.95** (**a**) BrO^- (**b**) BrO^- (**c**) HPO_4^{2-}

16.97 (**a**) True (**b**) False. In a series of acids that have the same central atom, acid strength increases with the number of nonprotonated oxygen atoms bonded to the central atom. (**c**) False. H_2Te is a stronger acid than H_2S because the H—Te bond is longer, weaker, and more easily ionized than the H—S bond.

16.93 $NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$. Ammonia, NH_3, acts as an Arrhenius base because it increases the concentration of hydroxide ion, OH^-, in aqueous solution. It acts like a Brønsted-Lowry base because it is a proton, H^+, acceptor. It acts like a Lewis base because it is an electron pair donor. **16.101** $K = 3.3 \times 10^7$

16.105 pH $= 7.01$ (not 5.40, from the typical calculation, which does not make sense.) Usually we assume that $[H^+]$ and $[OH^-]$ from the autoionization of water do not contribute to the overall $[H^+]$ and $[OH^-]$. However, for acid or base solute concentrations less than $1 \times 10^{-6}\,M$, the autoionization of water produces significant $[H^+]$ and $[OH^-]$ and we must consider it when calculating pH.

16.108 (**a**) $pK_b = 9.16$ (**b**) pH $= 3.07$ (**c**) pH $= 8.77$

16.112 Nicotine, protonated; caffeine, neutral base; strychnine, protonated; quinine, protonated **16.115** 6.0×10^{13} H^+ ions

16.117 (**a**) To the precision of the reported data, the pH of rainwater 40 years ago was 5.4, no different from the pH today. With extra significant figures, $[H^+] = 3.61 \times 10^{-6}\,M$, pH $= 5.443$ (**b**) A 20.0-L bucket of today's rainwater contains 0.02 L (with extra significant figures, 0.0200 L) of dissolved CO_2.

Chapter 17

17.1 The middle box has the highest pH. For equal amounts of acid HX, the greater the amount of conjugate base X^-, the smaller the amount of H^+ and the higher the pH. **17.7** (**a**) The red curve corresponds to the more concentrated acid solution. (**b**) On the titration curve of a weak acid, pH $= pK_a$ at the volume halfway to the equivalence point. Reading the pK_a values from the two curves, the red curve has the smaller pK_a and the larger K_a.**17.9** (**a**) The right-most diagram represents the solubility of $BaCO_3$ as HNO_3 is added. (**b**) The left-most diagram represents the solubility of $BaCO_3$ as Na_2CO_3 is added. (**c**) The center diagram represents the solubility of $BaCO_3$ as $NaNO_3$ is added. **17.13** Statement (**a**) is most correct.

17.15 (**a**) $[H^+] = 1.8 \times 10^{-5}\,M$, pH $= 4.73$ (**b**) $[OH^-] = 4.8 \times 10^{-5}\,M$, pH $= 9.68$ (**c**) $[H^+] = 1.4 \times 10^{-5}\,M$, pH $= 4.87$ **17.17** (**a**) 4.5% ionization (**b**) 0.018% ionization**17.19** Only solution (**a**) is a buffer.

17.21 (**a**) pH $= 3.82$ (**b**) pH $= 3.96$**17.23** (**a**) pH $= 5.26$

(**b**) $Na^+(aq) + CH_3COO^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow$

$CH_3COOH(aq) + Na^+(aq) + Cl^-(aq)$

(**c**) $CH_3COOH(aq) + Na^+(aq) + OH^-(aq) \longrightarrow$

$CH_3COO^-(aq) + H_2O(l) + Na^+(aq)$

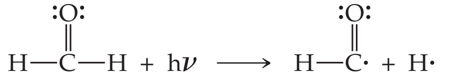
17.25 (**a**) pH $= 1.58$ (**b**) 36 g NaF **17.27** (**a**) pH $= 4.86$ (**b**) pH $= 5.0$ (**c**) pH $= 4.71$ **17.29** (**a**) $[HCO_3^-]/[H_2CO_3] = 11$ (**b**) $[HCO_3^-]/[H_2CO_3] = 5.4$ **17.31** 360 mL of $0.10\,M$ HCOONa, 640 mL of $0.10\,M$ HCOOH **17.33** (**a**) Curve B (**b**) pH at the approximate equivalence point of curve A $= 8.0$, pH at the approximate equivalence point of curve B $= 7.0$ (**c**) For equal volumes of A and B, the concentration of acid B is greater, since it requires a larger volume of base to reach the equivalence point. (**d**) The pK_a value of the weak acid is approximately 4.5 **17.35** (**a**) False (**b**) true (**c**) true

17.37 (**a**) Above pH 7 (**b**) below pH 7 (**c**) at pH 7 **17.39** The second color change of thymol blue is in the correct pH range to show the equivalence point of the titration of a weak acid with a strong base. **17.41** (**a**) 42.4 mL NaOH soln (**b**) 35.0 mL NaOH soln (**c**) 29.8 mL NaOH soln **17.43** (**a**) pH = 1.54 (**b**) pH = 3.30 (**c**) pH = 7.00 (**d**) pH = 10.69 (**e**) pH = 12.74 **17.45** (**a**) pH = 2.78 (**b**) pH = 4.74 (**c**) pH = 6.58 (**d**) pH = 8.81 (**e**) pH = 11.03 (**f**) pH = 12.42 **17.47** (**a**) pH = 7.00 (**b**) $[HONH_3^+] = 0.100\,M$, pH = 3.52 (**c**) $[C_6H_5NH_3^+] = 0.100\,M$, pH = 2.82 **17.49** (**a**) True (**b**) false (**c**) false (**d**) true **17.51** $K_{sp} = [Ag^+][I^-]$; $K_{sp} = [Sr^{2+}][SO_4^{2-}]$; $K_{sp} = [Fe^{2+}][OH^-]^2$; $K_{sp} = [Hg_2^{2+}][Br^-]^2$ **17.53** (**a**) $K_{sp} = 7.63 \times 10^{-9}$ (**b**) $K_{sp} = 2.7 \times 10^{-9}$ (**c**) 5.3×10^{-4} mol $Ba(IO_3)_2$/L **17.55** $K = 2.3 \times 10^{-9}$ **17.57** (**a**) 7.1×10^{-7} mol AgBr/L (**b**) 1.7×10^{-11} mol AgBr/L (**c**) 5.0×10^{-12} mol AgBr/L **17.59** (**a**) The amount of $CaF_2(s)$ on the bottom of the beaker increases. (**b**) The $[Ca^{2+}]$ in solution increases. (**c**) The $[F^-]$ in solution decreases. **17.61** (**a**) 1.4×10^3 g $Mn(OH)_2$/L (**b**) 0.014 g/L (**c**) 3.6×10^{-7} g/L **17.63** More soluble in acid: (**a**) $ZnCO_3$ (**b**) ZnS (**d**) AgCN (**e**) $Ba_3(PO_4)_2$ **17.65** $[Ni^{2+}] = 1.3 \times 10^{-6}\,M$, $[Ni(NH_3)_6^{2+}] = 0.0964\,M$ **17.67** (**a**) 9.1×10^{-9} mol AgI per L pure water (**b**) $K = K_{sp} \times K_f = 8 \times 10^4$ (**c**) 0.0500 mol AgI per L 0.100 *M* NaCN **17.69** (**a**) $Q < K_{sp}$; no $Ca(OH)_2$ precipitates (**b**) $Q < K_{sp}$; no Ag_2SO_4 precipitates **17.71** pH = 11.5 **17.73** AgI will precipitate first, at $[I^-] = 4.2 \times 10^{-13}\,M$. **17.75** AgCl will precipitate first. **17.77** Ag^+ (Group 1) and Mg^{2+} (Group 4) are definitely absent. Al^{3+} (Group 3) is definitely present and Na^+ (Group 5) is possibly present. **17.79** (**a**) Make the solution acidic with 0.2 *M* HCl; saturate with H_2S. CdS will precipitate; ZnS will not. (**b**) Add excess base; $Fe(OH_3)(s)$ precipitates, but Cr^{3+} forms the soluble complex $Cr(OH)_4^-$. (**c**) Add $(NH_4)_2HPO_4$; Mg^{2+} precipitates as $MgNH_4PO_4$; K^+ remains soluble. (**d**) Add 6 *M* HCl; precipitate Ag^+ as AgCl(*s*); Mn^{2+} remains soluble. **17.81** (**a**) Base is required to increase $[PO_4^{3-}]$ so that the solubility product of the metal phosphates of interest is exceeded and the phosphate salts precipitate. (**b**) K_{sp} for the cations in group 3 is much larger; to exceed K_{sp}, a higher $[S^{2-}]$ is required. (**c**) They should all redissolve in strongly acidic solution. **17.83** Choice (b) is correct. **17.89** (**a**) 6.5 mL glacial acetic acid, 5.25 g CH_3COONa **17.91** (**a**) The molar mass of the acid is 94.6 g/mol. (**b**) $K_a = 1.4 \times 10^{-3}$ **17.97** (**a**) $[Pb^{2+}] = 2.7 \times 10^{-7}\,M$ (**b**) 56 ppb Pb^{2+} (**c**) The solubility of $PbCO_3$ increases as pH is lowered. (**d**) A saturated solution of lead carbonate, with a lead concentration of 56 ppb, exceeds the EPA acceptable lead level of 15 ppb. **17.102** The solubility of $Mg(OH)_2$ in 0.50 *M* NH_4Cl is 0.11 mol/L **17.108** $[OH^-] \geq 1.0 \times 10^{-2}\,M$ or pH $\geq$ 12.02 **17.115** (**a**) $[Ag^+]$ from AgCl is 1.4×10^3 ppb or 1.4 ppm. (**b**) $[Ag^+]$ from AgBr is 76 ppb. (**c**) $[Ag^+]$ from AgI is 0.98 ppb. AgBr would maintain $[Ag^+]$ in the correct range.

Chapter 18

18.1 (**a**) A volume greater than 22.4 L (**b**) No. The relative volumes of one mole of an ideal gas at 50 km and 85 km depend on the temperature and pressure at the two altitudes. From Figure **18.1**, the gas will occupy a much larger volume at 85 km than at 50 km. (**c**) We expect gases to behave most ideally in the thermosphere, around the stratopause and in the troposphere at low altitude. **18.3** (**a**) A = troposphere, 0–10 km; B = stratosphere, 12–50 km; C = mesosphere, 50–85 km (**b**) Ozone is a pollutant in the troposphere and filters UV radiation in the stratosphere. (**c**) The troposphere (**d**) Only region C in the diagram is involved in an aurora borealis, assuming a narrow "boundary" between the stratosphere and mesosphere at 50 km. (**e**) The concentration of water vapor is greatest near Earth's surface in region A and decreases with altitude. Water's single bonds are susceptible to photodissociation in regions B and C, so its concentration is likely to be very low in these regions. The relative concentration of CO_2, with strong double bonds, increases in regions B and C, because it is less susceptible to photodissociation. **18.4** The Sun **18.6** $CO_2(g)$ dissolves in seawater to form $H_2CO_3(aq)$. The basic pH of the ocean encourages ionization of $H_2CO_3(aq)$ to form $HCO_3^-(aq)$ and $CO_3^{2-}(aq)$. Under the correct conditions, carbon is removed from the ocean as $CaCO_3(s)$ (sea shells, coral, chalk cliffs). As carbon is removed, more $CO_2(g)$ dissolves to maintain the balance of complex and interacting acid-base and precipitation equilibria. **18.7** Above ground, evaporation of petroleum gases and hydrogen sulfide at the well head, evaporation of volatile petroleum products and organic compounds from waste ponds, as well as leakage and overflow from the ponds are potential sources of contamination. Below ground, petroleum gases and fracking liquid can migrate into groundwater, both deep and shallow aquifers. **18.9** (**a**) Its temperature profile (**b**) troposphere, 0 to 12 km; stratosphere, 12 to 50 km; mesosphere, 50 to 85 km; thermosphere, 85 to 110 km **18.11** (**a**) The partial pressure of O_3 is 3.0×10^{-7} atm (2.2×10^{-4} torr). (**b**) 7.3×10^{15} O_3 molecules/1.0 L air **18.13** 8.7×10^{16} CO molecules/1.0 L air **18.15** (**a**) 570 nm (**b**) visible electromagnetic radiation **18.17** (**a**) *Photodissociation* is cleavage of a bond such that two neutral species are produced. *Photoionization* is absorption of a photon with sufficient energy to eject an electron, producing an ion and the ejected electron. (**b**) Photoionization of O_2 requires 1205 kJ/mol. Photodissociation requires only 495 kJ/mol. At lower elevations, high-energy short-wavelength solar radiation has already been absorbed. Below 90 km, the increased concentration of O_2 and the availability of longer-wavelength radiation cause the photodissociation process to dominate. **18.19** (**a**) A wavelength of 145 nm is in the ultraviolet portion of the electromagnetic spectrum. (**b**) The energy of one mole of 145-nm photons is 826 kJ. This is more than enough energy to photodissociate O_2, but not enough energy to photoionize O_2. **18.21** Ozone depletion reactions, which involve only O_3, O_2, or O (oxidation state = 0), do not involve a change in oxidation state for oxygen atoms. Reactions involving ClO and one of the oxygen species with a zero oxidation state do involve a change in the oxidation state of oxygen atoms. **18.23** (**a**) A chlorofluorocarbon is a compound that contains chlorine, fluorine, and carbon, while a hydrofluorocarbon is a compound that contains hydrogen, fluorine, and carbon. An HFC contains hydrogen in place of the chlorine present in a CFC. (**b**) HFCs are potentially less harmful to the ozone layer than CFCs because their photodissociation does not produce Cl atoms, which catalyze the destruction of ozone. **18.25** (**a**) The maximum wavelength of a single photon that will break a C—F bond is 247 nm. The maximum wavelength of a single photon that will break a C—Cl bond is 365 nm. (**b**) We don't expect the photodissociation of C—F bonds to be significant in the lower atmosphere. (The photodissociation of C—Cl bonds will be significant.) **18.27** $2\,NO_2(g) + H_2O(l) \rightleftharpoons HNO_2 + HNO_3(aq)$; $2\,NO(g) + O_2 + H_2O(l) \rightleftharpoons HNO_2(aq) + HNO_3$ **18.29** (**a**) $H_2SO_4(aq) + CaCO_3(s) \longrightarrow CaSO_4(s) + H_2O(l) + CO_2(g)$ (**b**) The $CaSO_4(s)$ would be much less reactive with acidic solution, since it would require a strongly acidic solution to shift the relevant equilibrium to the right: $CaSO_4(s) + 2H^+(aq) \rightleftharpoons Ca^{2+}(aq) + 2HSO_4^-(aq)$. $CaSO_4$ would protect $CaCO_3$ from attack by acid rain, but it would not provide the structural strength of limestone. **18.31** (**a**) Ultraviolet (**b**) 357 kJ/mol (**c**) The average C—H bond energy from Table **8.3** is 413 kJ/mol. The C—H bond energy in CH_2O, 357 kJ/mol, is less than the "average" C—H bond energy.

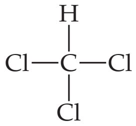
(**d**)

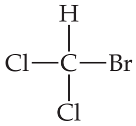


$$H{-}\overset{\overset{\displaystyle :\!O\!:}{\|}}{C}{-}H + h\nu \longrightarrow H{-}\overset{\overset{\displaystyle :\!O\!:}{\|}}{C}\cdot + H\cdot$$

18.33 (**a**) 235 W/m². (**b**) Four sources, surface radiation, evapotranspiration, incoming solar radiation and convective heating, transfer energy to the atmosphere. Surface radiation makes the largest contribution and convective heating the smallest. (**c**) Of the 519 W/m^2 absorbed by the atmosphere, 324 W/m^2 are radiated back to the surface. The percentage is 62.4%. **18.35** 0.099 M Na^+ **18.37** (**a**) 3.22 × 10^3 gH_2O (**b**) The final temperature is 43.4 °C. **18.39** 4.361 × 10^5 g CaO **18.41** (**a**) The total cation charge is 5.866 = 5.9 C; the total anion charge is 5.847 = 5.8 C. The two numbers vary in the third significant figure. This is not surprising, because the molarities of the various ions are given to two significant figures. **18.43** (**a**) $CO_2(g)$, HCO_3^-, $H_2O(l)$, SO_4^{2-}, NO_3^-, HPO_4^{2-}, $H_2PO_4^-$ (**b**) $CH_4(g)$, $H_2S(g)$, $NH_3(g)$, $PH_3(g)$, **18.45** 25.1 g O_2 **18.47** 0.42 mol $Ca(OH)_2$, 0.18 mol Na_2CO_3 **18.49** (**a**) *Trihalomethanes* are the by-products of water chlorination; they contain one central carbon atom bound to one hydrogen and three halogen atoms.

(**b**)

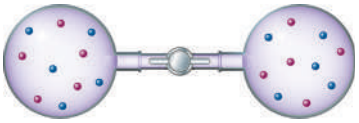




18.51 The fewer steps in a process, the less waste is generated. Processes with fewer steps require less energy at the site of the process and for subsequent cleanup or disposal of waste. **18.53** (**a**) H_2O (**b**) It is better to prevent waste than to treat it. Atom economy. Less hazardous chemical synthesis and inherently safer for accident prevention. Catalysis and design for energy efficiency. Raw materials should be renewable. **18.55** (**a**) Water as a solvent, by criteria 5, 7, and 12. (**b**) Reaction temperature of 500 K, by criteria 6, 12, and 1. (**c**) Sodium chloride as a by-product, according to criteria 1, 3, and 12. **18.59** Multiply equations 18.7 and 18.9 by a factor of 2. Add these two equations to a third equation, $O(g) + O(g) \longrightarrow O_2(g)$. 2 CI ($g$) and 2 ClO ($g$) cancel from each side of the resulting equation to produce equation 18.10. **18.62** (**a**) A CFC has C—Cl bonds and C—F bonds. In an HFC, the C—Cl bonds are replaced by C—H bonds. (**b**) Stratospheric lifetime is significant because, the longer a halogen-containing molecule exists in the stratosphere, the greater the likelihood that it will encounter light with energy sufficient to dissociate a carbon-halogen bond. Free halogen atoms are the bad actors in ozone destruction. (**c**) HFCs have replaced CFCs because it is infrequent that light with energy sufficient to dissociate a C—F bond will reach an HFC molecule. F atoms are much less likely than Cl atoms to be produced by photodissociation in the stratosphere. (**d**) The main disadvantage of HFCs as replacements for CFCs is that they are potent greenhouse gases. **18.64** (**a**) $CH_4(g) + 2\,O_2(g) \longrightarrow CO_2(g) + 2\,H_2O(g)$ (**b**) $2\,CH_4(g) + 3\,O_2(g) \longrightarrow 2\,CO_2(g) + 4\,H_2O(g)$ (**c**) 9.5 L of dry air **18.68** 7.1 × 10^8 m^2 **18.70** (**a**) CO_3^{2-} is a relatively strong Brønsted–Lowry base and produces OH^- in aqueous solution. If $[OH^-(aq)]$ is sufficient for the reaction quotient to exceed K_{sp} for $Mg(OH)_2$, the solid will precipitate. (**b**) At these ion concentrations, $Q > K_{sp}$ and $Mg(OH)_2$ will precipitate. **18.72** (**a**) 2.5 × 10^7 ton CO_2, 4.2 × 10^5 ton SO_2 (**b**) 4.3 × 10^5 ton $CaSO_3$ **18.74** (**a**) $\mathrm{H{-}\underset{\cdot\cdot}{\ddot{O}}{-}H} \longrightarrow \mathrm{H\cdot} + \mathrm{\cdot\underset{\cdot\cdot}{\ddot{O}}{-}H}$ (**b**) 258 nm (**c**) The overall reaction is $O_3(g) + O(g) \longrightarrow 2O_2(g)$. $OH(g)$ is the catalyst in the overall reaction because it is consumed and then reproduced. **18.75** The enthalpy change for the first step is −141 kJ, for the second step, −249 kJ, for the overall reaction, −390 kJ. **18.77** (**a**) Rate = $k[O_3][H]$ (**b**) $k_{avg} = 1.13 \times 10^{44}\,M^{-1}\,s^{-1}$ **18.80** (**a**) Process (**i**) is greener because it involves neither the toxic reactant phosgene nor the by-product HCl. (**b**) Reaction (**i**): C in CO_2 is linear with *sp* hybridization; C in R—N=C=O is linear with *sp* hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. Reaction (ii): C in $COCl_2$ is trigonal planar with sp^2 hybridization; C in R—N=C=O is linear with *sp* hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. (**c**) The greenest way to promote formation of the isocyanate is to remove by-product, either water or HCl, from the reaction mixture.

Chapter 19

19.1 (**a**)

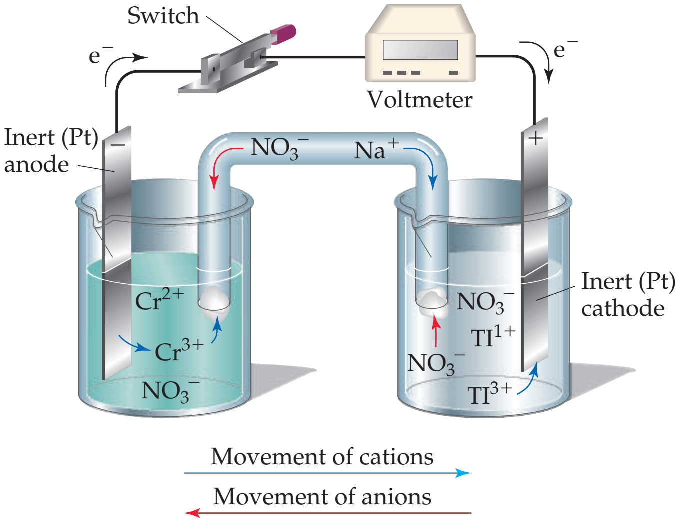


(**b**) $\Delta H = 0$ for mixing ideal gases. ΔS is positive because the disorder of the system increases. (**c**) The process is spontaneous and therefore irreversible. (**d**) Since $\Delta H = 0$, the process does not affect the entropy of the surroundings. **19.4** Both ΔH and ΔS are positive. The net change in the chemical reaction is the breaking of five blue-blue bonds. Enthalpies for bond breaking are always positive. There are twice as many molecules of gas in the products, so ΔS is positive for this reaction. **19.7** Statements (b) and (c) are true. **19.10** (**a**) True (**b**) false (**c**) false (**d**) false (**e**) true **19.11** Spontaneous: a, b, c, d; nonspontaneous: e **19.13** (**a**) True, assuming that the forward and reverse processes occur at the same conditions. (**b**) false (**c**) false (**d**) true (**e**) false **19.15** (**a**) Endothermic (**b**) above 100 °C (**c**) below 100 °C (**d**) at 100 °C **19.17** Statement (a) is true because ΔE is a state function. Statements (b) and (c) are true because it is specified that the reversible path has been taken in both directions. **19.19** (**a**) The melting of water is spontaneous at temperatures above 0 °C. (**b**) The process is irreversible. (**c**) The process is endothermic—the ice absorbs heat when it melts, so $\Delta H > 0$. (**d**) The entropy of liquid water is greater than that of ice, so $\Delta S > 0$ for the process. **19.21** (**a**) True (**b**) false (**c**) true (**d**) false **19.23** (**a**) Entropy increases. (**b**) 89.2 J/K **19.25** (**a**) False (**b**) true (**c**) false **19.27** (**a**) Positive ΔS (**b**) $\Delta S = 1.02$ J/K (**c**) Statements (i) and (iii) are true. **19.29** (**a**) Yes, the expansion is spontaneous. (**b**) As the ideal gas expands into the vacuum, there is nothing for it to “push back,” so no work is done. Mathematically, $w = -P_{ext}\Delta V$. Since the gas expands into a vacuum, $P_{ext} = 0$ and $w = 0$. (**c**) The “driving force” for the expansion of the gas is the increase in entropy. **19.31** (**a**) An increase in temperature produces more available microstates for a system. (**b**) A decrease in volume produces fewer available microstates for a system. (**c**) Going from liquid to gas, the number of available microstates increases. **19.33** (**a**) ΔS is positive. (**b**) S of the system clearly increases in 19.11 (**a**), (**b**), and (**e**); it clearly decreases in 19.11 (**c**). The definition of the system in (**d**) is problematic. **19.35** S increases in (**a**) and (**c**); S decreases in (**b**). **19.37** (**a**) False (**b**) true (**c**) false (**d**) true **19.39** (**a**) $Ar(g)$ (**b**) $He(g)$ at 1.5 atm (**c**) 1 mol of $Ne(g)$ in 15.0 L (**d**) $CO_2(g)$ **19.41** (**a**) $\Delta S < 0$ (**b**) $\Delta S > 0$ (**c**) $\Delta S < 0$ (**d**) $\Delta S \approx 0$ **19.43** Statements (b) and (c) are true. **19.45** (**a**) $Br_2(g)$ (**b**) $C_2H_5OH(l)$ (**c**) $SiCl_4(l)$ (**d**) $Fe(s)$ at 500 °C **19.47** (**a**) $Sc(g)$ will have the higher standard enthalpy at 25 °C. $Sc(s)$, 34.6 J/mol − K; $Sc(g)$, 174.7 J/mol − K. (**b**) $NH_3(g)$ will have the higher standard enthalpy at 25 °C. $NH_3(g)$, 192.5 J/mol − K; $NH_3(aq)$, 111.3 J/mol − K (**c**) $O_3(g)$ will have the higher standard enthalpy at 25 °C. $O_2(g)$, 205.0 J/K; $O_3(g)$, 237.6 J/K. (**d**) C (graphite) will have the higher standard enthalpy at 25 °C. C (diamond), 2.43 J/mol-K; C (graphite), 5.69 J/mol-K. **19.49** $\Delta S > 0$ for the dissolution of $NH_4NO_3(s)$ in water. **19.51** (**a**) $\Delta S° = -120.6$ J/K. $\Delta S°$ is negative because there are fewer moles of gas in the products. (**b**) $\Delta S° = +176.6$ J/K. $\Delta S°$ is positive because there are more moles of gas in the products. (**c**) $\Delta S° = +152.39$ J/K. $\Delta S°$ is positive because the product contains more total particles and more moles of gas. (**d**) $\Delta S° = +91.9$ J/K. $\Delta S°$ is positive because there are more moles of gas in the products. **19.53** (**a**) Yes. $\Delta G = \Delta H - T\Delta S$ (**b**) No. If ΔG is positive, the process is nonspontaneous. (**c**) No. There is no relationship between ΔG and rate of reaction. **19.55** (**a**) Exothermic (**b**) ΔS° is negative; the reaction leads to a decrease in disorder. (**c**) $\Delta G^\circ = -9.9$ kJ (**d**) If all reactants and products are present in their standard states, the reaction is spontaneous in the forward direction at this temperature. **19.57** (**a**) $\Delta H^\circ = -546.60$ kJ, $\Delta S^\circ = 14.1$ J/K, $\Delta G^\circ = -550.80$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -550.80$ kJ (**b**) $\Delta H^\circ = -106.7$ kJ, $\Delta S^\circ = -142.3$ J/K $\Delta G^\circ = -64.0$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -64.3$ kJ (**c**) $\Delta H^\circ = -508.3$ kJ, $\Delta S^\circ = -179$ J/K, $\Delta G^\circ = -465.8$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -455.0$ kJ. The discrepancy in ΔG° values is due to experimental uncertainties in the tabulated thermodynamic data. (**d**) $\Delta H^\circ = -165.9$ kJ, $\Delta S^\circ = 1.3$ J/K, $\Delta G^\circ = -166.1$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -166.3$ kJ **19.59** (**a**) $\Delta G^\circ = -140.0$ kJ, spontaneous (**b**) $\Delta G^\circ = +104.70$ kJ, nonspontaneous (**c**) $\Delta G^\circ = +146$ kJ, nonspontaneous (**d**) $\Delta G^\circ = -156.7$ kJ, spontaneous **19.61** (**a**) $2\,C_8H_{18}(l) + 25\,O_2(g) \longrightarrow 16\,CO_2(g) + 18\,H_2O(l)$ (**b**) Because ΔS° is positive, ΔG° is more negative than ΔH°. **19.63** (**a**) The forward reaction is spontaneous at low temperatures but becomes nonspontaneous at higher temperatures. (**b**) The reaction is nonspontaneous in the forward direction at all temperatures. (**c**) The forward reaction is nonspontaneous at low temperatures but becomes spontaneous at higher temperatures.**19.65** $\Delta S > 60.8$ J/K **19.67** (**a**) $T = 330$ K (**b**) nonspontaneous**19.69** (**a**) $\Delta H^\circ = 155.7$ kJ, $\Delta S^\circ = 171.4$ kJ. Since ΔS° is positive, ΔG° becomes more negative with increasing temperature. (**b**) $\Delta G^\circ = 19$ kJ. The reaction is not spontaneous under standard conditions at 800 K (**c**) $\Delta G^\circ = -15.7$ kJ. The reaction is spontaneous under standard conditions at 1000 K. **19.71** (**a**) $T_b = 353.6\ \text{K} = 80.4\ ^\circ\text{C}$ (**b**) From the *NIST Chemistry Webbook* (https://webbook.nist.gov/chemistry/) , $T_b = 353.3$ K. The values are remarkably close; the small difference is due to deviation from ideal behavior by $C_6H_6(g)$ and experimental uncertainty in the boiling point measurement and the thermodynamic data. **19.73** (**a**) $C_2H_2(g) + \frac{5}{2}O_2(g) \longrightarrow 2\,CO_2(g) + H_2O(l)$ (**b**) -1300.2 kJ of heat produced/mol C_2H_2 burned (**c**) $w_{\text{max}} = -1235.9$ kJ/mol C_2H_2 **19.75** (**a**) ΔG decreases; it becomes more negative. (**b**) ΔG increases; it becomes more positive. (**c**) ΔG increases; it becomes more positive. **19.77** (**a**) $\Delta G^\circ = -5.40$ kJ (**b**) $\Delta G = 0.30$ kJ **19.79** (**a**) $\Delta G^\circ = -15.79$ kJ, $K = 590$ (**b**) $\Delta G^\circ = 8.2$ kJ, $K = 0.036$ (**c**) $\Delta G^\circ = -500.3$ kJ, $K = 5 \times 10^{87}$ **19.81** $\Delta H^\circ = 269.3$ kJ, $\Delta S^\circ = 0.1719$ kJ/K (**a**) $P_{CO_2} = 6.0 \times 10^{-39}$ atm (**b**) $P_{CO_2} = 1.6 \times 10^{-4}$ atm **19.83** (**a**) $HNO_2(aq) \rightleftharpoons H^+(aq) + NO_2^-(aq)$ (**b**) $\Delta G^\circ = 19.1$ kJ (**c**) $\Delta G = 0$ at equilibrium (**d**) $\Delta G = -2.7$ kJ **19.85** (**a**) The thermodynamic quantities T, E, and S are state functions. (**b**) The quantities q and w depend on the path taken. (**c**) There is only one *reversible* path between states. (**d**) $\Delta E = q_{\text{rev}} + w_{\text{max}}$, $\Delta S = q_{\text{rev}}/T$. **19.88** Statements (a) and (b) are true. **19.93** (**a**) $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \longrightarrow NH_3(g)$; $C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g)$ (**b**) In the first reaction, ΔG_f° will be more positive (less negative) than ΔH_f°. (**c**) Condition (iii), when ΔS_f° is negative. **19.98** (**a**) For the oxidation of glucose, $\Delta H^\circ = -2803.0$ kJ and $\Delta G^\circ = -2878.8$ kJ. (**b**) For the anaerobic decomposition of glucose, $\Delta H^\circ = -68.0$ kJ and $\Delta G^\circ = -226.4$ kJ. (**c**) $K = 5 \times 10^{39}$. **19.103** (**a**) For any given total pressure, the condition of equal moles of the two gases can be achieved at some temperature. For individual gas pressures of 1 atm and a total pressure of 2 atm, the mixture is at equilibrium at 328.5 K or 55.5 °C. (**b**) 333.0 K or 60 °C (**c**) 374.2 K or 101.2 °C

Chapter 20

20.1 In this analogy, the electron is analogous to the proton (H^+). Redox reactions can be viewed as electron-transfer reactions, just as acid-base reactions can be viewed as proton-transfer reactions. Oxidizing agents are themselves reduced; they gain electrons. A strong oxidizing agent would be analogous to a strong base. **20.3** (**a**) The process represents oxidation. (**b**) The electrode is the anode. (**c**) When a neutral atom loses a valence electron, the radius of the resulting cation is smaller than the radius of the neutral atom. **20.7** (**a**) The sign of ΔG° is positive. (**b**) The equilibrium constant is less than one. (**c**) No. An electrochemical cell based on this reaction cannot accomplish work on its surroundings. **20.10** (**a**) Zinc is the anode. (**b**) The energy density of the silver oxide battery is most similar to the nickel-cadmium battery. The molar masses of the electrode materials and the cell potentials for these two batteries are most similar. **20.13** (**a**) *Oxidation* is the loss of electrons. (**b**) Electrons appear on the products' side (right side). (**c**) The *oxidant* is the reactant that is reduced. (**d**) An *oxidizing agent* is the substance that promotes oxidation; it is the oxidant. **20.15** (**a**) True (**b**) false (**c**) true **20.17** (**a**) (**i**) Reactants: I, +5; O, −2; C +2; O, −2. Products: I, 0; C, +4; O, −2 (ii) The total number of electrons transferred is 10. (**b**) (**i**) Reactants: Hg, +2; N, −2; H, +1. Products: Hg, 0; N, 0; H, +1. (ii) The total number of electrons transferred is 4. (**c**) (**i**) Reactants: H, +1; S, −2; N, +5; O, −2. Products: S, 0; N, +2; O, −2; H, +1; O, −2. (ii) The total electrons transferred is 6. **20.19** (**a**) No oxidation-reduction (**b**) Iodine is oxidized from −1 to +5; chlorine is reduced from +1 to −1. (**c**) Sulfur is oxidized from +4 to +6; nitrogen is reduced from +5 to +2. **20.21** (**a**) $TiCl_4(g) + 2\,Mg(l) \longrightarrow Ti(s) + 2\,MgCl_2(l)$ (**b**) $Mg(l)$ is oxidized; $TiCl_4(g)$ is reduced. (**c**) $Mg(l)$ is the reductant; $TiCl_4(g)$ is the oxidant. **20.23** (**a**) $Sn^{2+}(aq) \longrightarrow Sn^{4+}(aq) + 2\,e^-$, oxidation (**b**) $TiO_2(s) + 4\,H^+(aq) + 2\,e^- \longrightarrow Ti^{2+}(aq) + 2\,H_2O(l)$, reduction (**c**) $ClO_3^-(aq) + 6\,H^+(aq) + 6\,e^- \longrightarrow Cl_2(aq) + 3\,H_2O(l)$, reduction (**d**) $N_2(g) + 8\,H^+(aq) + 6\,e^- \longrightarrow 2\,NH_4^+(aq)$, reduction **20.25** (**a**) $O_2(g) + 2\,H_2O(l) + 4\,e^- \longrightarrow 4\,OH^-(aq)$, reduction (**b**) $Mn^{2+}(aq) + 4\,OH^-(aq) \longrightarrow MnO_2(s) + 2\,H_2O(l) + 2\,e^-$, oxidation (**c**) $Cr(OH)_3(s) + 5\,OH^-(aq) \longrightarrow CrO_4{}^{2-}(aq) + 4\,H_2O(l) + 3\,e^-$, oxidation (**d**) $N_2H_4(aq) + 4\,OH^-(aq) \longrightarrow N_2(g) + 4\,H_2O(l) + 4\,e^-$, oxidation **20.27** (**a**) $Cr_2O_7{}^{2-}(aq) + I^-(aq) + 8\,H^+(aq) \longrightarrow 2\,Cr^{3+}(aq) + IO_3{}^-(aq) + 4\,H_2O(l)$; oxidizing agent, $Cr_2O_7^{2-}$; reducing agent, I^- (**b**) $I_2(s) + 5\,OCl^-(aq) + H_2O(l) \longrightarrow 2\,IO_3{}^-(aq) + 5\,Cl^-(aq) + 2\,H^+(aq)$; oxidizing agent, OCl^-; reducing agent, l_2 (**c**) $2\,MnO_4{}^-(aq) + Br^-(aq) + H_2O(l) \longrightarrow 2\,MnO_2(s) + BrO_3{}^-(aq) + 2\,OH^-(aq)$; oxidizing agent, $MnO_4{}^-$; reducing agent, Br^- **20.27** (**a**) $3\,NO_2{}^-(aq) + Cr_2O_7{}^{2-}(aq) + 8\,H^+(aq) \longrightarrow 2\,Cr^{3+}(aq) + 3\,NO_3{}^-(aq) + 4\,H_2O(l)$; oxidizing agent, $Cr_2O_7{}^{2-}$; reducing agent, $NO_2{}^-$ (**b**) $2\,Cr_2O_7{}^{2-}(aq) + 3\,CH_3OH(aq) + 16\,H^+(aq) \longrightarrow 3\,HCOOH(aq) + 4\,Cr^{3+}(aq) + 11\,H_2O(l)$; oxidizing agent, $Cr_2O_7{}^{2-}$; reducing agent, CH_3OH (**c**) $NO_2{}^-(aq) + 2\,Al(s) + 2\,H_2O(l) \longrightarrow NH_4{}^+(aq) + 2\,AlO_2{}^-(aq)$; oxidizing agent, $NO_2{}^-$; reducing agent, Al **20.31** (**a**) False (**b**) true (**c**) true **20.33** (**a**) $Fe(s)$ is oxidized, $Ag^+(aq)$ is reduced. (**b**) $Ag^+(aq) + e^- \longrightarrow Ag(s)$; $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$. (**c**) $Fe(s)$ is the anode, $Ag(s)$ is the cathode. (**d**) $Fe(s)$ is negative; $Ag(s)$ is positive. (**e**) Electrons flow from the Fe electrode (−) toward the Ag electrode (+). (**f**) Cations migrate toward the $Ag(s)$ cathode; anions migrate toward the $Fe(s)$ anode. **20.35** (**a**) One *volt* is the potential energy difference required to impart 1 J of energy to a charge of 1 coulomb. (**b**) Yes. All voltaic cells involve spontaneous redox reactions that produce positive cell potentials or emfs. **20.37** (**a**) $2\,H^+(aq) + 2\,e^- \longrightarrow H_2(g)$ (**b**) $H_2(g) \longrightarrow 2\,H^+(aq) + 2\,e^-$ (**c**) A *standard* hydrogen electrode, SHE, is a hydrogen electrode where the components are at standard conditions, 1 M $H^+(aq)$ and $H_2(g)$ at 1 atm, such that $E^\circ = 0\ V$. (**c**) The platinum foil in a SHE serves as an inert electron carrier and a solid reaction surface. **20.39** (**a**) $Cr^{2+}(aq) \longrightarrow Cr^{3+}(aq) + e^-$; $Tl^{3+}(aq) + 2\,e^- \longrightarrow Tl^+(aq)$ (**b**) $E^\circ_{\text{red}} = 0.78\ V$

(**c**)



20.41 (**a**) $E° = 0.82$ V (**b**) $E° = 1.89$ V (**c**) $E° = 1.21$ V (**d**) $E° = 0.62$ V **20.39** (**a**) $3\,Ag^+(aq) + Cr(s) \longrightarrow 3\,Ag(s) + Cr^{3+}(aq)$, $E° = 1.54$ V (**b**) Two of the combinations have *e* equal $E°$ values: $2\,Ag^+(aq) + Cu(s) \longrightarrow 2\,Ag(s) + Cu^{2+}(aq)$, $E° = 0.46$ V; $3\,Ni^{2+}(aq) + 2\,Cr(s) \longrightarrow 3\,Ni(s) + 2\,Cr^{3+}(aq)$, $E° = 0.46$ V **20.43** (**a**) Anode, Sn(*s*); cathode, Cu(*s*). (**b**) The copper electrode gains mass as Cu is plated out, and the tin electrode loses mass as Sn is oxidized. (**c**) $Cu^{2+}(aq) + Sn(s) \longrightarrow Cu(s) + Sn^{2+}(aq)$. (**d**) $E° = 0.48$ V **20.47** (**a**) Mg(*s*) (**b**) Ca(*s*) (**c**) $H_2(g)$ (**d**) $IO_3^-(aq)$ **20.49** (**a**) $Cl_2(aq)$, oxidant (**b**) $MnO_4^-(aq)$, acidic, oxidant (**c**) Ba(*s*) reductant (**d**) Zn(*s*), reductant **20.51** (**a**) $Cu^{2+}(aq) < O_2(g) < Cr_2O_7^{2-}(aq) < Cl_2(g) < H_2O_2(aq)$ (**b**) $H_2O_2(aq) < I^-(aq) < Sn^{2+}(aq) < Zn(s) < Al(s)$ **20.53** Al and $H_2C_2O_4$ **20.55** (**a**) $2\,Fe^{2+}(aq) + S_2O_6^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + 2\,H_2SO_3(aq)$; $2\,Fe^{2+}(aq) + N_2O(aq) + 2\,H^+(aq) \longrightarrow 2\,Fe^{3+}(aq) + N_2(g) + H_2O(l)$; $Fe^{2+}(aq) + VO_2^+(aq) + 2\,H^+(aq) \longrightarrow Fe^{3+}(aq) + VO^{2+}(aq) + H_2O(l)$ (**b**) $E° = -0.17$ V, $\Delta G° = 33$ kJ; $E° = -2.54$ V, $\Delta G° = 4.90 \times 10^2$ kJ; $E° = 0.23$ V, $\Delta G° = -22$ kJ (**c**) $K = 1.8 \times 10^{-6} = 10^{-6}$; $K = 1.2 \times 10^{-86} = 10^{-86}$; $K = 7.8 \times 10^3 = 8 \times 10^3$ **20.57** $\Delta G° = 21.8$ kJ, $E°_{cell} = -0.113$ V **20.59** (**a**) $E° = 0.16$ V, $K = 2.54 \times 10^5 = 3 \times 10^5$ (**b**) $E° = 0.28$ V, $K = 2.93 \times 10^9 = 3 \times 10^9$ (**c**) $E° = 0.44$ V, $K = 2.40 \times 10^{74} = 10^{74}$ **20.61** (**a**) $K = 9.8 \times 10^2$ (**b**) $K = 1 \times 10^6$(**c**) $K = 1 \times 10^9$ **20.63** $w_{max} = 1.3 \times 10^2$ kJ/mol Sn; 8.3×10^4 J/75.0 g Sn **20.65** (**a**) In the Nernst equation, $Q = 1$ if all reactants and products are at standard conditions. (**b**) Yes. The Nernst equation is applicable to cell emf at nonstandard conditions, so it must be applicable at temperatures other than 298 K. Values of $E°$ at temperatures other than 298 K are required. And, there is a variable for T in the second term. If the short-hand form of the equation, Equation **20.18**, is used, a coefficient other than 0.0592 is required. **20.67** (**a**) *E* decreases (**b**) *E* decreases (**c**) *E* decreases (**d**) no effect **20.65** (**a**) $E° = 0.48$ V (**b**) $E = 0.52$ V (**c**) $E = 0.46$ V **20.71** (**a**) $E° = 0.46$ V (**b**) $E = 0.37$ V **20.73** (**a**) The compartment with $[Zn^{2+}] = 1.00 \times 10^{-2}\,M$ is the anode. (**b**) $E° = 0$ (**c**) $E = 0.0668$ V (**d**) In the anode compartment $[Zn^{2+}]$ increases; in the cathode compartment $[Zn^{2+}]$ decreases. **20.75** $E° = 0.76$ V, pH $= 1.6$ **20.77** (**a**) 464 g PbO_2 (**b**) 3.74×10^5 C of charge transferred **20.79** (**a**) The anode (**b**) $E° = 3.50$ V (**c**) The emf of the battery, 3.5 V, is exactly the standard cell potential calculated in part (**b**). (**d**) At ambient conditions, $E \approx E°$, so $\log Q \approx 1$. Assuming that the value of $E°$ is relatively constant with temperature, the value of the second term in the Nernst equation is approximately zero at 37 °C, and $E \approx 3.5$ V. **20.81** (**a**) The cell emf will have a smaller value. (**b**) NiMH batteries use an alloy such as $ZrNi_2$ as the anode material. This eliminates the use and disposal problems associated with Cd, a toxic heavy metal. **20.83** (**a**) $Li_{0.5}CoO_2$, which we can write as $LiCo_2O_4$ (**b**) the average oxidation state of cobalt is +3.5, which represents a 50:50 mixture of Co^{3+} and Co^{4+} (**c**)4.9×10^3 C of electricity delivered on full discharge of a fully charged battery **20.85** (**a**) The spontaneous reaction in the hydrogen fuel cell is hydrogen gas plus oxygen gas makes water. (**b**) $E° = 1.23$ V **20.87** (**a**) anode: $Fe(s) \longrightarrow Fe^{2+}(aq) + 2\,e^-$; cathode: $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$ (**b**) $2\,Fe^{2+}(aq) + 3\,H_2O(l) + 3\,H_2O(l) \longrightarrow Fe_2O_3 \cdot 3\,H_2O(s) + 6\,H^+(aq) + 2\,e^-$; $O_2(g) + 4\,H^+(aq) + 4\,e^- \longrightarrow 2\,H_2O(l)$ **20.89** (**a**) Mg is called a "sacrificial anode" because it has a more negative $E°_{red}$ than the pipe metal and is preferentially oxidized when the two are coupled. It is sacrificed to preserve the pipe. (**b**) $E°_{red}$ for Mg^{2+} is −2.37 V, more negative than most metals present in pipes, including Fe and Zn. **20.91** (**a**) +3 (**b**) +8/3 or +2.67 (**c**) 2 Fe(III) and 1 Fe(II) **20.93** (**a**) *Electrolysis* is an electrochemical process driven by an outside energy source. (**b**) By definition, electrolysis reactions are nonspontaneous. (**c**) $2\,Cl^-(l) \longrightarrow Cl_2(g) + 2\,e^-$ (**d**) When an aqueous solution of NaCl undergoes electrolysis, sodium metal is not formed because H_2O is preferentially reduced to form $H_2(g)$ **20.95** (**a**) 236 g Cr(*s*) (**b**) 2.51 A **20.97** (**a**) 4.0×10^5 g Li (**b**) The minimum voltage required to drive the electrolysis is +4.41 V. **20.99** (**a**) $2\,Ni^+(aq) \longrightarrow Ni(s) + Ni^{2+}(aq)$ (**b**) $3\,MnO_4^{2-}(aq) + 4\,H^+(aq) \longrightarrow 2\,MnO_4^-(aq) + MnO_2(s) + 2\,H_2O(l)$ (**c**) $3\,H_2SO_3(aq) \longrightarrow S(s) + 2\,HSO_4^-(aq) + 2\,H^+(aq) + H_2O(l)$ (**d**) $Cl_2(aq) + 2\,OH^-(aq) \longrightarrow Cl^-(aq) + ClO^-(aq) + H_2O(l)$ **20.101** (**a**) $E° = 0.682$ V, spontaneous (**b**) $E° = -0.82$ V, nonspontaneous (**c**) $E° = 0.93$ V, spontaneous (**d**) $E° = 0.19$ V, spontaneous **20.107** (**a**) By analogy to O in hydroxide (OH^-) and in alcohol (R—OH), the oxidation state of S in a thiol (R—SH) is −2. (**b**) By analogy to O in peroxide (—O—O—), the oxidation state of S in a disulfide (—S—S—) is −1. (**c**) The oxidation number of S becomes more positive and the thiols are oxidized. (**d**) Converting a disulfide to two thiols is the reverse of the process described in part (**c**). In order to reduce the disulfide, a reducing agent must be added to the solution. (**e**) When two thiols (R—SH) react to form a disulfide (R—S—S—R), the H atoms are probably removed by base before the oxidizing agent does its work. **20.109** 3×10^4 kWh required **20.112** (**a**) $E° = -0.03$ V, (**b**) cathode: $Ag^+(aq) + e^- \longrightarrow Ag(s)$; anode: $Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$ (**c**) $\Delta S° = 148.5$ J. Because $\Delta S°$ is positive, $\Delta G°$ will become more negative and $E°$ will become more positive as temperature is increased. **20.114** K_{sp} for AgSCN is $1.0 \times 10^{12} = 10^{12}$

Chapter 21

21.1 (**a**) ^{24}Ne; outside; reduce neutron-to-proton ratio via β decay (**b**) ^{32}Cl; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (**c**) ^{108}Sn; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (**d**) ^{216}Po; outside; nuclei with $Z \geq 84$ usually decay via α emission. **21.6** (**a**) 7 min (**b**) 0.1 min^{-1} (**c**) 30% (3/10) of the sample remains after 12 min. (**d**) $^{88}_{41}Nb$ **21.7** (**a**) $^{10}_{5}B$, $^{11}_{5}B$; $^{12}_{6}C$, $^{13}_{6}C$; $^{14}_{7}N$, $^{15}_{7}N$; $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$; $^{19}_{9}F$ (**b**) $^{14}_{6}C$ (**c**) $^{11}_{6}C$, $^{13}_{7}N$, $^{15}_{8}O$, $^{18}_{9}F$ (**d**) $^{11}_{6}C$ **21.9** (**a**) $^{54}_{24}Cr$, 24 protons, 32 neutrons (**b**) ^{193}Tl; 81 protons, 112 neutrons (**c**) ^{38}Ar; 18 protons, 20 neutrons **21.11** (**a**) $^{1}_{0}n$ (**b**) $^{4}_{2}He$ or α (**c**) $^{0}_{0}\gamma$ or γ **21.13** (**a**) $^{90}_{37}Rb \longrightarrow {}^{90}_{38}Sr + {}^{0}_{-1}e$

(b) ${}^{72}_{34}\text{Se} + {}^{0}_{-1}\text{e}$ (orbital electron) $\longrightarrow {}^{72}_{33}\text{As}$ **(c)** ${}^{76}_{33}\text{Kr} \longrightarrow {}^{76}_{35}\text{Br} + {}^{0}_{1}\text{e}$ **(d)** ${}^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + {}^{4}_{2}\text{He}$ **21.15** **(a)** ${}^{211}_{82}\text{Pb} \longrightarrow {}^{211}_{83}\text{Bi} + {}^{0}_{-1}\beta$ **(b)** ${}^{50}_{25}\text{Mn} \longrightarrow {}^{50}_{24}\text{Cr} + {}^{0}_{1}\text{e}$ **(c)** ${}^{179}_{74}\text{W} + {}^{0}_{-1}\text{e} \longrightarrow {}^{179}_{73}\text{Ta}$ **(d)** ${}^{230}_{90}\text{Th} \longrightarrow {}^{266}_{88}\text{Ra} + {}^{4}_{2}\text{He}$ **21.17** 7 alpha emissions, 4 beta emissions **21.19** **(a)** Positron emission (for low atomic numbers, positron emission is more common than electron capture) **(b)** beta emission **(c)** beta emission **(d)** beta emission **21.21** **(a)** ${}^{40}_{19}\text{K}$, radioactive, odd proton, odd neutron; ${}^{39}_{19}\text{K}$, stable, 20 neutrons is a magic number **(b)** ${}^{208}_{83}\text{Bi}$, radioactive, odd proton, odd neutron; ${}^{209}_{83}\text{Bi}$, stable, 126 neutrons is a magic number **(c)** ${}^{65}_{28}\text{Ni}$, radioactive, high neutron-to-proton ratio; ${}^{58}_{28}\text{Ni}$ stable, even proton, even neutron **21.23** **(a)** ${}^{4}_{2}\text{He}$ **(c)** ${}^{40}_{20}\text{Ca}$ **(e)** ${}^{126}_{82}\text{Pb}$ **21.25** Statement **(a)** is the best explanation. **21.27** Statement **(b)** is the best explanation. **21.29** **(a)** ${}^{252}_{98}\text{Cf} + {}^{10}_{5}\text{B} \longrightarrow 3\,{}^{1}_{0}\text{n} + {}^{259}_{103}\text{Lr}$ **(b)** $\text{H}^{2}_{1} + {}^{3}_{2}\text{He} \longrightarrow {}^{4}_{2}\text{He} + {}^{1}_{1}\text{H}$ **(c)** ${}^{1}_{1}\text{H} + {}^{11}_{5}\text{B} \longrightarrow 3\,{}^{4}_{2}\text{He}$ **(d)** ${}^{122}_{53}\text{I} \longrightarrow {}^{122}_{54}\text{Xe} + {}^{0}_{-1}\text{e}$ **(e)** ${}^{59}_{26}\text{Fe} \longrightarrow {}^{0}_{-1}\text{e} + {}^{59}_{27}\text{Co}$ **21.31** **(a)** ${}^{238}_{92}\text{U} + {}^{4}_{2}\text{He} \longrightarrow {}^{241}_{94}\text{Pu} + {}^{1}_{0}\text{n}$ **(b)** ${}^{14}_{7}\text{N} + {}^{4}_{2}\text{He} \longrightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{H}$ **(c)** ${}^{56}_{26}\text{Fe} + {}^{4}_{2}\text{He} \longrightarrow {}^{60}_{29}\text{Cu} + {}^{0}_{-1}\text{e}$ **21.33** Statements (a) and (b) are true. **21.35** When the watch is 50 years old, only 6% of the tritium remains. The dial will be dimmed by 94%. **21.37** The source must be replaced after 2.18 yr or 26.2 months; this corresponds to August 2018. **21.39** **(a)** 1.1×10^{11} alpha particles emitted in 5.0 min **(b)** 9.9 mCi **21.41** $k = 1.21 \times 10^{-4}\,\text{yr}^{-1}$; $t = 4.3 \times 10^{3}$ yr **21.43** $k = 5.46 \times 10^{-10}\,\text{yr}^{-1}$; $t = 3.0 \times 10^{9}$ yr **21.45** 9×10^{6} kJ **21.47** $\Delta m = 0.2414960$ amu, $\Delta E = 3.604129 \times 10^{-11}\,\text{J}/{}^{27}\text{Al}$ nucleus required, $8.044234 \times 10^{13}\,\text{J}/100\,\text{g}\;{}^{27}\text{Al}$ **21.49** **(a)** Nuclear mass: ${}^{2}\text{H}$, 2.013553 amu; ${}^{4}\text{He}$, 4.001505 amu; ${}^{6}\text{Li}$, 6.0134771 amu **(b)** nuclear binding energy: ${}^{2}\text{H}$, 3.564×10^{-13} J; ${}^{4}\text{He}$, 4.5336×10^{-12} J; ${}^{6}\text{Li}$, 5.12602×10^{-12} J. **(c)** binding energy/nucleon: ${}^{2}\text{H}$, 1.782×10^{-13} J/nucleon; ${}^{4}\text{He}$, 1.1334×10^{-12} J/nucleon; ${}^{6}\text{Li}$, 8.54337×10^{-13} J/nucleon. (d) Of the three isotopes, ${}^{4}\text{He}$ has the largest binding energy per nucleon; this anomaly is apparent in Figure **12.12**. The trend in binding energy/nucleon agrees with the curve in the figure. 21.51 (a) 1.71×10^{-5} kg/d **(b)** $2.1 \times 10^{-8}\,\text{g}\;{}^{235}\text{U}$ 21.53 (a) Nucleus (b), ${}^{51}\text{V}$ has the largest binding energy per nucleon. **21.55** **(a)** Statement (ii) is the best explanation of why NaI is a good choice for the source of iodine. **(b)** The radioactive iodine will decay to 0.01% of the original amount in approximately 107 days. **21.57** **(a)** Characteristics (ii) and (iv) are required for a fuel in a nuclear power plant. **(b)** ${}^{235}\text{U}$ **21.59** The *control rods* in a nuclear reactor regulate the flux of neutrons to keep the reaction chain self-sustaining and also to prevent the reactor core from overheating. They are composed of materials such as boron or cadmium that absorb neutrons.

21.61 **(a)** ${}^{2}_{1}\text{H} + {}^{2}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{1}_{0}\text{n}$ **(b)** ${}^{239}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{133}_{51}\text{Sb} + {}^{98}_{41}\text{Nb} + 9\,{}^{1}_{0}\text{n}$ **21.63** $\Delta m = 0.006627$ g/mol; $\Delta E = 5.956 \times 10^{11}\,\text{J} = 5.956 \times 10^{8}\,\text{kJ/mol}\;{}^{1}_{1}\text{H}$ **21.65** **(a)** Boiling water reactor **(b)** fast breeder reactor **(c)** gas-cooled reactor **21.67** Hydrogen abstraction: $\text{RCOOH} + \bullet\text{OH}^{-} \longrightarrow \text{RCOO}\bullet + \text{H}_2\text{O}$; deprotonation: $\text{RCOOH} + \text{OH}^{-} \longrightarrow \text{RCOO}^{-} + \text{H}_2\text{O}$. Hydroxyl radical is more toxic to living systems because it produces other radicals when it reacts with molecules in the organism. Hydroxide ion, OH^{-}, on the other hand, will be readily neutralized in the buffered cell environment. The acid–base reactions of OH^{-} are usually much less disruptive to the organism than the chain of redox reactions initiated by OH radical **21.69** **(a)** 5.3×10^{8} dis/s, 5.3×10^{8} Bq **(b)** 6.1×10^{2} mrad, 6.1×10^{-3} Gy **(c)** 5.8×10^{3} mrem, 5.8×10^{-2} Sv **21.72** ${}^{210}_{82}\text{Pb}$ **21.74** **(a)** ${}^{36}_{17}\text{Cl} \longrightarrow {}^{36}_{18}\text{Ar} + {}^{0}_{-1}\text{e}$ **(b)** Statement (iii) is the best explanation: ${}^{35}\text{Cl}$ and ${}^{37}\text{Cl}$ both have an odd number of protons but an even number of neutrons. ${}^{36}\text{Cl}$ has an odd number of protons and neutrons, so it is less stable than the other two isotopes.

21.76 **(a)** ${}^{6}_{3}\text{Li} + {}^{56}_{28}\text{Ni} \longrightarrow {}^{62}_{31}\text{Ga}$ **(b)** ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \longrightarrow {}^{147}_{62}\text{Sm} + {}^{147}_{54}\text{Xe}$ **(c)** ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \longrightarrow {}^{116}_{46}\text{Pd} + {}^{56}_{28}\text{Ni}$ **(d)** ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \longrightarrow {}^{70}_{30}\text{Zn} + 4\,{}^{1}_{0}\text{n} + 2\,{}^{102}_{41}\text{Nb}$ **21.82** ${}^{7}\text{Be}$, 8.612×10^{-13} J/nucleon; ${}^{9}\text{Be}$, 1.035×10^{-12} J/nucleon; ${}^{10}\text{Be}$: 1.042×10^{-12} J/nucleon. The binding energies/ nucleon for ${}^{9}\text{Be}$ and ${}^{10}\text{Be}$ are very similar; that for ${}^{10}\text{Be}$ is slightly higher.

Chapter 22

22.1 Statement **(c)** is correct. **22.3** Molecules **(b)** and **(d)** will have the seesaw structure shown in the figure. **22.6** The graph shows the trend in **(c)** density for the group 6A elements. Going down the family, atomic mass increases faster than atomic volume (radius), and density increases. **22.9** The compound on the left, with the strained three-membered ring, will be the most generally reactive. The larger the deviation from ideal bond angles, the more strain in the molecule and the more generally reactive it is. **22.11** **(a)** nonmetal **(b)** metal **(c)** metal **(d)** nonmetal **(e)** metal, **(f)** nonmetal. **22.13** **(a)** O **(b)** Br **(c)** Ba **(d)** O **(e)** Co **(f)** Br **22.15** Statements **(b)** and **(d)** are true. **22.17** **(a)** $\text{NaOCH}_3(s) + \text{H}_2\text{O}(l) \longrightarrow \text{NaOH}(aq) + \text{CH}_3\text{OH}(aq)$ **(b)** $\text{CuO}(s) + 2\,\text{HNO}_3(aq) \longrightarrow \text{Cu(NO}_3)_2(aq) + \text{H}_2\text{O}(l)$ **(c)** $\text{WO}_3(s) + 3\,\text{H}_2(g) \xrightarrow{\Delta} \text{W}(s) + 3\,\text{H}_2\text{O}(g)$ **(d)** $4\,\text{NH}_2\text{OH}(l) + \text{O}_2(g) \longrightarrow 6\,\text{H}_2\text{O}(l) + 2\,\text{N}_2(g)$ **(e)** $\text{Al}_4\text{C}_3(s) + 12\,\text{H}_2\text{O}(l) \longrightarrow 4\,\text{Al(OH)}_3(s) + 3\,\text{CH}_4(g)$ **22.19** **(a)** ${}^{1}_{1}\text{H}$, protium; ${}^{2}_{1}\text{H}$, deuterium; ${}^{3}_{1}\text{H}$, tritium **(b)** in order of decreasing natural abundance: protium > deuterium > tritium **(c)** Tritium, ${}^{3}_{1}\text{H}$, is radioactive. **(d)** ${}^{3}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{He} + {}^{0}_{-1}\text{e}$ **22.21** Like other elements in group 1A, hydrogen has only one valence electron and its most common oxidation number is +1. **22.23** **(a)** $\text{NaH}(s) + \text{H}_2\text{O}(l) \longrightarrow \text{NaOH}(aq) + \text{H}_2(g)$ **(b)** $\text{Fe}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{Fe}^{2+}(aq) + \text{H}_2(g) + \text{SO}_4{}^{2-}(aq)$ **(c)** $\text{H}_2(g) + \text{Br}_2(g) \longrightarrow 2\,\text{HBr}(g)$ **(d)** $2\,\text{Na}(l) + \text{H}_2(g) \longrightarrow 2\,\text{NaH}(s)$ **(e)** $\text{PbO}(s) + \text{H}_2(g) \xrightarrow{\Delta} \text{Pb}(s) + \text{H}_2\text{O}(g)$ **22.25** **(a)** Ionic **(b)** molecular **(c)** metallic **22.27** Vehicle fuels produce energy via combustion reactions. The combustion of hydrogen is very exothermic and its only product, H_2O, is a non-pollutant. **22.29** Xenon has a lower ionization energy than argon; because the valence electrons are not as strongly attracted to the nucleus, they are more readily promoted to a state in which the atom can form bonds with fluorine. Also, Xe is larger, more polarizable and can more easily accommodate an expanded octet of electrons. **22.31** **(a)** Ca(OBr)_2, Br, +1 **(b)** HBrO_3, Br, +5 **(c)** XeO_3, Xe, +6 **(d)** $\text{ClO}_4{}^{-}$, Cl, +7 **(e)** HIO_2, I,+3 **(f)** IF_5; I,+5; F, −1 **22.33** **(a)** iron(III) chlorate, Cl, +5; **(b)** chlorous acid, Cl, +3 **(c)** xenon hexafluoride, F, −1 **(d)** bromine pentafluoride; Br, +5; F, −1 **(e)** xenon oxide tetrafluoride, F, −1 **(f)** iodic acid, I, +5 **22.35** **(a)** van der Waals intermolecular attractive forces increase with increasing number of electrons in the atoms. **(b)** F_2 reacts with water: $\text{F}_2(g) + \text{H}_2\text{O}(l) \longrightarrow 2\,\text{HF}(g) + \text{O}_2(g)$. That is, fluorine is too strong an oxidizing agent to exist in water. **(c)** HF has extensive hydrogen bonding. **(d)** Oxidizing power is related to electronegativity. Electronegativity and oxidizing power decrease in the order given.

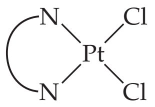
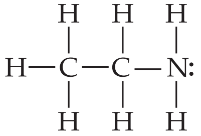
Chapter 23

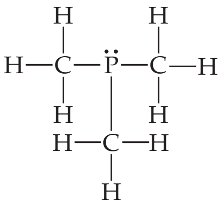
23.3



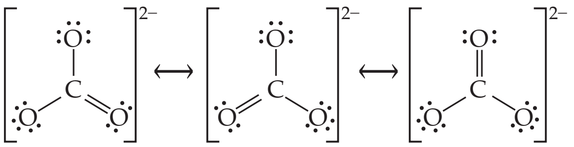
(**a**) Coordination number is 4 (**b**) coordination geometry is square planar (**c**) oxidation state is +2. **23.6** Molecules (1), (3), and (4) are chiral because their mirror images are not superimposible on the original molecules. **23.8** (**a**) Diagram (4) (**b**) diagram (1) (**c**) diagram (3) (**d**) diagram (2) **23.11** The lanthanide contraction explains trend (**c**). The lanthanide contraction is the name given to the decrease in atomic size due to the build-up in effective nuclear charge as we move through the lanthanides and beyond them. This effect offsets the expected increase in atomic size going from period 5 to period 6 transition elements. **23.13** (**a**) Ti^{2+}, $[Ar]3d^2$ (**b**) Ti^{4+}, $[Ar]$ (**c**) Ni^{2+}, $[Ar]3d^8$ (**d**) Zn^{2+}, $[Ar]3d^{10}$ **23.15** (**a**) Ti^{3+}, $[Ar]3d^1$ (**b**) Ru^{2+}, $[Kr]4d^6$ (**c**) Au^{3+}, $[Xe]4f^{14}5d^8$ (**d**) Mn^{4+}, $[Ar]3d^3$ **23.17** (**a**) The unpaired electrons in a paramagnetic material cause it to be weakly attracted into a magnetic field. **23.19** The diagram shows a material with misaligned spins that become aligned in the direction of an applied magnetic field. This is a paramagnetic material.
23.21 (**a**) *Primary valence* is roughly the same as oxidation number. Oxidation number is a broader term than ionic charge, but Werner's complexes contain metal ions where cation charge and oxidation number are equal. (**b**) Coordination number is the modern term for secondary valence. (**c**) NH_3 can serve as a ligand because it has an unshared electron pair, while BH_3 does not. Ligands are the Lewis base in metal–ligand interactions. As such, they must possess at least one unshared electron pair. **23.23** (**a**) +2 (**b**) 6 (**c**) 2 mol AgBr(s) will precipitate per mole of complex. **23.25** (**a**) Coordination number = 4, oxidation number = +2 (**b**) 5, +4 (**c**) 6, +3 (**d**) 5, +2 (**e**) 6, +3 (**f**) 4, +2 **23.27** (**a**) Monodentate ligand



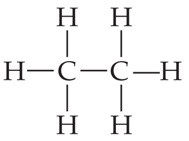
(**b**) monodentate ligand



(**c**) either monodentate or bidentate ligand

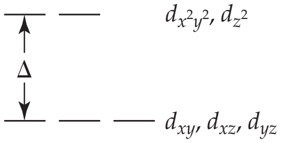


(**d**) unlikely to act as a ligand

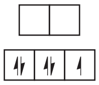


23.29 (**a**) *Ortho*-phenanthroline, *o*-phen, is bidentate (**b**) oxalate, $C_2O_4^{2-}$, is bidentate (**c**) ethylenediaminetetraacetate, EDTA, is hexadentate. This is an unusual, 7-coordinate, complex. (**d**) ethylenediamine, en, is bidentate. **23.31** (**a**) Acetonitrile (CH_3CN) (**b**) hydride ion (H^-) (**c**) carbon monoxide (CO) **23.33** False. The ligand is not typically a bidentate ligand. The entire molecule is planar and the benzene rings on either side of the two N atoms inhibit their approach in the correct orientation for chelation. **23.35** (**a**) $[Cr(NH_3)_6](NO_3)_3$ (**b**) $[Co(NH_3)_4CO_3]_2SO_4$ (**c**) $[Pt(en)_2C1_2]Br_2$ (**d**) $K[V(H_2O)_2Br_4]$ (**e**) $[Zn(en)_2][Hgl_4]$ **23.37** (**a**) tetraamminedichlororhodium(III) chloride (**b**) potassium hexachlorotitanate(IV) (**c**) tetrachlorooxomolybdenum(VI) (**d**) tetraaqua(oxalato)platinum (IV) bromide **23.39**(**a**) Complexes 1, 2 and 3 can have geometric isomers; they each have *cis-trans* isomers. (**b**) Complex 2 can have linkage isomers, owing to the presence of the nitrite ligand. (**c**) The *cis* geometric isomer of complex 3 can have optical isomers (**d**) Complex 1 can have coordination sphere isomers. It is the only complex with a counter ion that can also be a ligand. **23.41** Yes. No structural or stereoisomers are possible for a tetrahedral complex of the form MA_2B_2. The complex must be square planar with *cis* and *trans* geometric isomers. **23.43** (**a**) Unique structure, no other isomers (**b**) two geometric isomers, *trans* and *cis* isomers with 180° and 90° Cl—Ir—Cl angles, respectively (**c**) three geometric isomers; *trans* and *cis* isomers with 180° and 90° Cl—Fe—Cl angles, respectively; the *cis* isomer has enantiomers **23.45** (**a**) Not chiral (**b**) not chiral (**c**) chiral, has optical isomers **23.47** (**a**) Blue (**b**) $E = 3.26 \times 10^{-19}$ J/photon (**c**) $E = 196$ kJ/mol
23.49 (**a**) Diamagnetic. Zn^{2+}, $[Ar]3d^{10}$. There are no unpaired electrons. (**b**) Diamagnetic. Pd^{2+}, $[Kr]4d^8$. Square planar complexes with 8 *d*-electrons are usually diamagnetic, especially with a heavy metal center like Pd. (**c**) Paramagnetic. V^{3+}, $[Ar]3d^2$. The two *d*-electrons would be unpaired in any of the *d*-orbital energy level diagrams. **23.51** An electron in a *d* orbital with lobes that point directly at the ligands will have higher energy than an electron in a *d* orbital with lobes that do not point directly at the ligands.

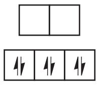
23.53 (**a**)



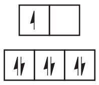
(**b**) The magnitude of Δ and the energy of the *d*-*d* transition for a d^1 complex are equal. (**c**) $\Delta = 220$ kJ/mol **23.55** (**a**) Both minerals contain Cu^{2+}, $[Ar]3d^9$. (**b**) Azurite will probably have the larger Δ. It absorbs orange visible light, which has shorter wavelengths than the red light absorbed by malachite. **23.57** (**a**) Ti^{3+}, d^1 (**b**) Co^{3+}, d^6 (**c**) Ru^{3+}, d^5 (**d**) Mo^{5+}, d^1 (**e**) Re^{3+}, d^4 **23.59** Yes. A weak-field ligand leads to a small Δ value and a small *d*-orbital splitting energy. If the splitting energy of a complex is smaller than the energy required to pair electrons in an orbital, the complex is high spin. **23.61** (**a**) Mn, $[Ar]4s^23d^5$; Mn^{2+}, $[Ar]3d^5$; 1 unpaired electron



(**b**) Ru, $[Kr]5s^14d^7$; Ru^{2+}, $[Kr]4d^6$; 0 unpaired electrons

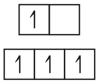


(**c**) Rh, $[Kr]5s^14d^8$; Rh^{2+}, $[Kr]4d^7$; 1 unpaired electron



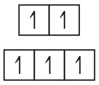
23.63 All complexes in this exercise are six-coordinate octahedral.

(**a**)



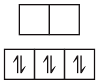
d^4, high spin

(**b**)



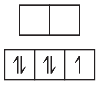
d^5, high spin

(**c**)



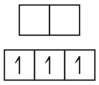
d^6, low spin

(**d**)



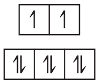
d^5, low spin

(**e**)



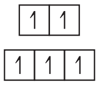
d^3

(**f**)



d^8

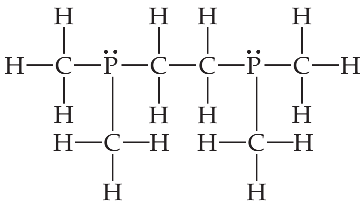
23.65



high spin

23.69 $[Pt(NH_3)_6]Cl_4$; $[Pt(NH_3)_4Cl_2]C1_2$; $[Pt(NH_3)_3Cl_3]C1$; $[Pt(NH_3)_2Cl_4]$; $K[Pt(NH_3)Cl_5]$

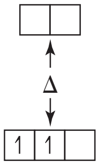
23.73 (**a**)



(**b**) The dmpe ligand is bidentate, binding through the two P atoms. (**c**) The oxidation state of Mo is zero. (**d**) $Mo(CO)_4(dmpe)$ is *not* chiral as it can be superimposed on its mirror image. **23.76** (**a**) Iron (**b**) magnesium (**c**) iron (**d**) copper **23.78** (**a**) Pentacarbonyliron(0) (**b**) The oxidation state of iron must be zero. (**c**) Two. One isomer has CN in an axial position and the other has it in an equatorial position.

23.80

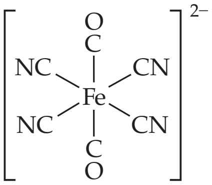
(**a**)



d^2

(**b**) Statement (ii) explains the colors of these complexes: an electron is excited from the t_2 orbitals to the *e* orbitals. (**c**) $[V(H_2O)_6]^{3+}$ will absorb light with higher energy because it has a larger Δ than $[VF_6]^{3-}$. H_2O is in the middle of the spectrochemical series and causes a larger Δ than F^-, a weak-field ligand. **23.82** $[Co(NH_3)_6]^{3+}$, yellow; $[Co(H_2O)_6]^{2+}$, pink; $[CoCl_4]^{2-}$, blue

23.83 (**a**)

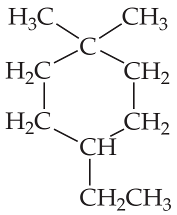


(**b**) sodium dicarbonyltetracyanoferrate(II) (**c**) +2, 6 *d*-electrons (**d**) We expect the complex to be low spin. Cyanide (and carbonyl) are high on the spectrochemical series, which means the complex will have a large Δ splitting, characteristic of low-spin complexes. **23.93** (**a**) Yes, the oxidation state of Co is +3 in both complexes. (**b**) When compound B reacts with $AgNO_3(aq)$, white $AgBr(s)$ precipitates. (**c**) When compound A reacts with $BaCl_2(aq)$, white $BaSO_4(s)$ precipitates. (**d**) Compounds A and B are coordination sphere isomers. (**e**) Both compounds are strong electrolytes. **23.94** $\Delta E = 3.02 \times 10^{-19}$ J/photon, $\lambda = 657$ nm. The complex will absorb in the visible around 660 nm and appear blue-green.

Chapter 24

24.1 Structures (**c**) and (**d**) are the same molecule. **24.7** (**a**) False (**b**) false (**c**) true (**d**) false **24.9** Numbering from the right on the condensed structural formula, C1 has trigonal-planar electron-domain geometry, 120° bond angles, and sp^2 hybridization; C2 and C5 have tetrahedral electron-domain geometry, 109° bond angles, and sp^3 hybridization; C3 and C4 have linear electron-domain geometry, 180° bond angles, and *sp* hybridization. **24.11** (**a**) One (**b**) ten (**c**) seven (**d**) five (**e**) two **24.13** (**a**) True (**b**) true (**c**) false (**d**) false (**e**) true (**f**) false (**g**) true **24.15** (**a**) 2,3-dimethylheptane (**b**) $CH_3CH_2CH_2C(CH_3)_3$

(**c**)

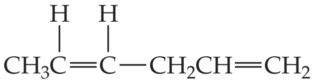


(**d**) 2,2,5-trimethylhexane (**e**) methylcyclobutane **24.17** (**a**) Unsaturated (**b**) Yes, all alkynes are unsaturated. **24.19** (**a**) $CH_3CH_2CH_2CH_2CH_3$, C_5H_{12}

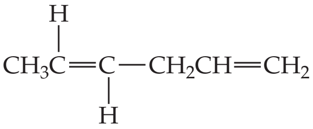
(**b**)  , C_5H_{10}

(**c**) $CH_2 = = CHCH_2\ CH_2\ CH_3$, C_5H_{10}
(**d**) $HC{\equiv}CCH_2CH_2CH_3$, C_5H_8
24.21 One possible structure is $CH{\equiv}C-CH{=}CH-C{\equiv}CH$
24.23 There are at least 46 structural isomers with the formula C_6H_{10}. A few of them are

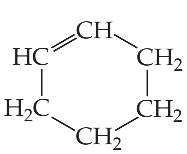
$CH_3CH_2CH_2CH_2C{\equiv}CH$ $CH_3CH_2CH_2C{\equiv}CCH_3$

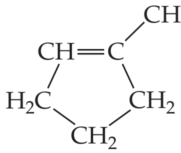


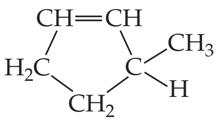
$CH_3\overset{\overset{H}{|}}{C}=\overset{\overset{H}{|}}{C}-CH_2CH=CH_2$



$CH_3\overset{\overset{H}{|}}{C}=\underset{\underset{H}{|}}{C}-CH_2CH=CH_2$





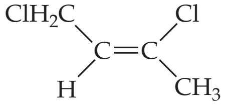


24.25

(**a**) 
(**b**) 
$CH_3CH_2CH_2-\overset{\overset{CH_3}{|}}{C}=CH-CH_2-\overset{\overset{CH_3}{|}}{CH}-CH_3$

(**c**) *cis*-6-methyl-3-octene (**d**) *para*-dibromobenzene (**e**) 4,4-dimethyl-1-hexyne **24.27** (**a**) True (**b**) true (**c**) false **24.29** (**a**) No

(**b**) 



(**c**) no (**d**) no **24.31** (**a**) True

(**b**) $CH_3CH_2CH{=}CH-CH_3 + Br_2 \longrightarrow$
2-pentene
$CH_3CH_2CH(Br)CH(Br)CH_3$
2, 3-dibromopentane

This is an addition reaction.

(**c**) 
$$C_6H_6 + Cl_2 \xrightarrow{FeCl_3} C_6H_4Cl_2$$

This is an substitution reaction.

24.33 The 60° C—C—C angles in the cyclopropane ring cause strain that provides a driving force for reactions that result in ring opening. There is no comparable strain in the five-membered or six-membered rings. (**b**) $C_2H_4(g) + HBr(g) \longrightarrow CH_3CH_2Br(l)$;

$$C_6H_6(l) + CH_3CH_2Br(l) \xrightarrow{AlCl_3} C_6H_5CH_2CH_3(l) + HBr(g)$$

24.35 Yes, this information suggests (but does not prove) that the reactions proceed in the same manner. That the two rate laws are first order in both reactants and second order overall indicates that the activated complex in the rate-determining step in each mechanism is bimolecular and contains one molecule of each reactant. This is usually an indication that the mechanisms are the same, but it does not rule out the possibility of different fast steps or a different order of elementary steps. **24.37** ΔH_{comb}/mol CH_2 for cyclopropane = 696.3 kJ, for cyclopentane = 663.4 kJ. $\Delta H_{comb}/CH_2$ group for cyclopropane is greater because C_3H_6 contains a strained ring. When combustion occurs, the strain is relieved and the stored energy is released. **24.39** (**a**) (iii) (**b**) (**i**) (**c**) (ii) (**d**) (iv) (**e**) (v)

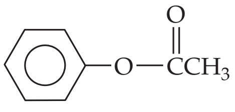
N-methylacetamide

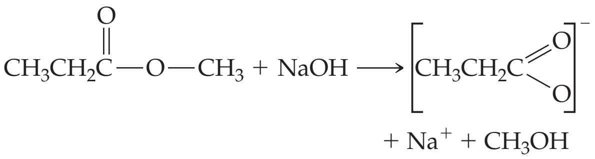
(c)



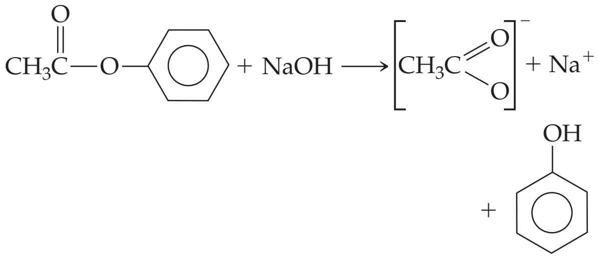
Phenylacetate

24.47

(a)

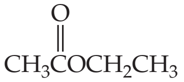


(b)



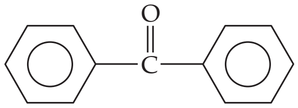
24.49 High melting and boiling points are indicators of strong intermolecular forces in the bulk substance. The presence of both —OH and —C=O groups in pure acetic acid leads us to conclude that it will be a strongly hydrogen-bonded substance. That the melting and boiling points of pure acetic acid are both higher than those of water, a substance we know to be strongly hydrogen-bonded, supports this conclusion. **24.51** (**a**) $CH_3CH_2CH_2CH(OH)CH_3$ (**b**) $CH_3CH(OH)CH_2OH$

(c)



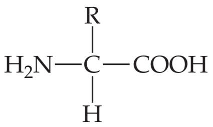
$CH_3\overset{\overset{\displaystyle O}{\|}}{C}OCH_2CH_3$

(d)



(**e**) $CH_3OCH_2CH_3$

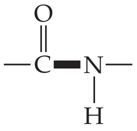
24.53 (**c**) There are two chiral carbon atoms in the molecule.



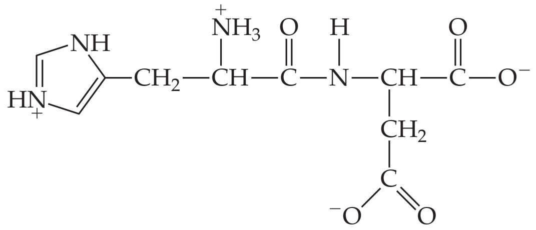
24.55 (**a**)

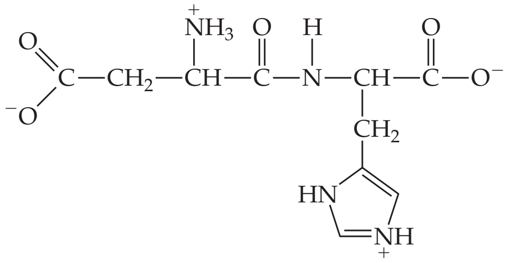
(**b**) In protein formation, amino acids undergo a condensation reaction between the amino group of one molecule and the carboxylic acid group of another to form the amide linkage.

(**c**) The bond that links amino acids in proteins is called the peptide bond. It is shown in bold in the figure below.

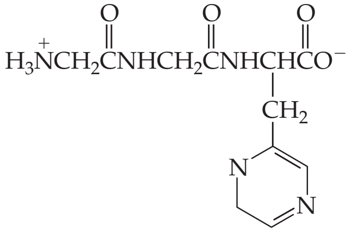


24.57

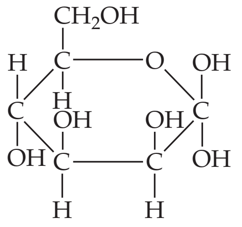


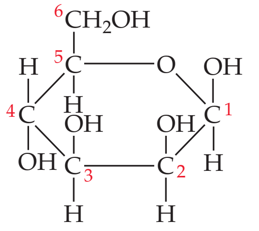


24.59 (**a**)



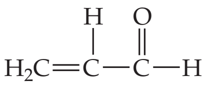
(**b**) Three tripeptides are possible: Gly-Gly-His, GGH; Gly-His-Gly, GHG; His-Gly-Gly, HGG **24.61** (**a**) True (**b**) false (**c**) false **24.63** (**a**) True (**b**) false (**c**) true **24.65** (**a**) The empirical formula of cellulose is $C_6H_{10}O_5$. (**b**) The six-membered ring form of glucose is the monomer unit that is the basis of the polymer cellulose. (**c**) Ether linkages connect the glucose monomer units in cellulose. **24.67** (**a**) Yes. (**b**) Four. In the linear form of mannose, the aldehydic carbon is C1. Carbon atoms 2, 3, 4, and 5 are chiral because they each carry four different groups. (**c**) Both the α (left) and β (right) forms are possible.



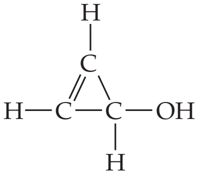


24.69 (**a**) False (**b**) true (**c**) true **24.71** *Purines*, with the larger electron cloud and molar mass, will have larger dispersion forces than *pyrimidines* in aqueous solution. **24.73** 5′–TACG–3′ **24.75** The complimentary strand for 5′–GCATTGGC–3′ is 3′–CGTAACCG–5′.

24.77



$H_2C{=}\overset{\overset{\displaystyle H}{|}}{C}-\overset{\overset{\displaystyle O}{\|}}{C}-H$



24.86 (**a**) One ketone and two alcohol functional groups; no chiral centers (**b**) One ketone and three alcohol functional groups; one chiral center (**c**) One carboxylic acid and one amine functional group; two chiral centers.

ANSWERS TO EXAM PREP QUESTIONS

Chapter 1

EP 1.1(**b**) molecules of a mixture of two different elements **EP 1.2** (**c**) A solid can be readily compressed. **EP 1.3** (**a**) the air that we breathe. **EP 1.4** (**d**) carbon **EP 1.5** (**b**) physical, extensive **EP 1.6** (**a**) Only one of the three is a physical change. **EP 1.7** (**d**) Distillation is a technique that depends on the differences in the tendencies of substances to form gases. **EP 1.8** (**e**) All three statements are correct. **EP 1.9** (**c**) Its kinetic energy increases and its gravitational potential energy decreases. **EP 1.10** (**d**) 4.0×10^6 cg **EP 1.11** (**b**) C < A < B **EP 1.12** (**a**) 19 bars **EP 1.13** (**c**) 15.5 kg **EP 1.14** (**d**) 1000 J **EP 1.15** (**b**) 2 **EP 1.16** (**c**) Statements i and iii are correct. **EP 1.17** (**c**) 4 **EP 1.18** (**d**) 4 **EP 1.19** (**e**) 2.9×10^2 g **EP 1.20** (**c**) 3 **EP 1.21** (**b**) 236 m/s **EP 1.22** (**b**) 0.961 kg/L **EP 1.23** (**b**) 9.02 mg

Chapter 2

EP 2.1 (**b**) the volume of space occupied by the electrons of the atom **EP 2.2** (**d**) ^{162}Ho **EP 2.3** (**c**) $^{63}_{30}$Cu **EP 2.4** (b) ^{63}Cu must be more abundant than ^{65}Cu **EP 2.5** (**c**) Se **EP 2.6** (**d**) C_4O_2, C_2O **EP 2.7** (**e**) Ce^{4+} **EP 2.8** (a) $\boldsymbol{Ti^{4+}}$ **EP 2.9** (**a**) CBr_4 **EP 2.10** (**d**) N **EP 2.11** (**a**) ClO_2^-, chlorate **EP 2.12** (**c**) Fe_2O_3, diiron trioxide **EP 2.13** (**b**) nitrous acid, HNO_3 **EP 2.14** (**a**) CS_2 **EP 2.15** (**d**) 2-methylbutane **EP 2.16** (**c**) C_3H_7 **EP 2.17** (**b**) 2

Chapter 3

EP 3.1 (**d**) 6 **EP 3.2** (**d**) 4 **EP 3.3** (**b**) $HCl(g) + NH_3(g) \longrightarrow NH_4Cl(s)$ **EP 3.4** (**d**) $2\,Ag_2O(s) \longrightarrow 4\,Ag(s) + O_2(g)$ **EP 3.5** (**b**) $2\,C_2H_4(OH)_2(l) + 5\,O_2(g) \longrightarrow 4\,CO_2(g) + 6\,H_2O(g)$ **EP 3.6** (**a**) 310.2 amu **EP 3.7** (**b**) 17.1% **EP 3.8** (**c**) 50 g sodium chloride **EP 3.9** (**b**) 2+ **EP 3.10** (**c**) 1.91×10^{23} **EP 3.11** (**d**) C_6H_{12} **EP 3.12** (**d**) $C_4H_8O_2$ **EP 3.13** (**a**) 3.18 g **EP 3.14** (**d**) 3.63 g **EP 3.15** (**d**) 14 mol $CH_3OH(l)$ **EP 3.16** (**a**) 1.20 g **EP 3.17** (**b**) 96% **EP 3.18** (**b**) O_2, 106 g **EP 3.19** (**b**) 72.6%

Chapter 4

EP 4.1 (**e**) 3.0. **EP 4.2** (**b**) $CaCO_3$ **EPQ 4.3** (e) No precipitate will form. **EP 4.4** (**a**) There is no reaction; all possible products are soluble. **EP 4.5** (**b**) hydrobromic acid **EP 4.6** (**d**) sodium nitrate **EP 4.7** (**d**) $NH_3(aq) + H^+(aq) \longrightarrow NH_4^+(aq)$ **EP 4.8** (**d**) H_2O_2 **EP 4.9** (**a**) Zinc is oxidized, and copper ion is reduced. **EP 4.10** (**b**) lithium **EP 4.11** (**c**) 3.91×10^{-2} *M* **EP 4.12** (**e**) 2:1 **EP 4.13** (**d**) 1.84 *M* **EP 4.14** (**b**) 8.75 mL **EP 4.15** (**b**) 19.5 mg **EP 4.16** (**c**) 0.163 *M* **EP 4.17** (**e**) 81.0%

Chapter 5

EP 5.1 (**c**) The electrostatic potential energy between potassium and bromide ions is positive. **EP 5.2** (**c**) $q < 0, w > 0$, the sign of ΔE cannot be determined from the information given **EP 5.3** (**c**) i and iii are true. **EP 5.4** (**d**) Because ΔH relates to heat, the value of ΔH depends on the path taken between two states. **EP 5.5** (**b**) −1.37 L-atm **EP 5.6** (**d**) exothermic, negative **EP 5.7** (**c**) i and iii are true. **EP 5.8** (**b**) −181 kJ **EP 5.9** (**c**) decreases, increases **EP 5.10** (**d**) −464 kJ > mol **EP 5.11** (**b**) 6.42 kJ > °C **EP 5.12** (**d**) −171.0 kJ **EP 5.13** (**c**) 131.3 kJ **EP 5.14** (**c**) $H_2(g) + \frac{1}{2}O_2(g) \longrightarrow H_2O(l) \qquad \Delta H = -286\text{ kJ}$ **EP 5.15** (**b**) −196.0 kJ **EP 5.16** (**c**) $2\Delta H_f^\circ[SO_3] = \Delta H_{rxn}^\circ + 2\Delta H_f^\circ[SO_2]$ **EP 5.17** (**e**) All three statements are true. **EP 5.18** (**a**) 242 kJ **EP 5.19** (**a**) 2 g carbohydrate and 0.1 g fat **EP 5.20** (**a**) A < B < C

Chapter 6

EP 6.1(**d**) 34.5 μm **EP 6.2** (**c**) frequency, speed **EP 6.3** (**b**) 0.16 m **EP 6.4** (**b**) Electrons will be emitted, and the maximum kinetic energies of those electrons will be greater than those emitted when irradiated with the red laser pointer. **EP 6.5** (**e**) $E = N_A\dfrac{hc}{\lambda}$ **EP 6.6** (**b**) They all have $n_f = 2$. **EP 6.7** (**b**) the uncertainty principle **EP 6.8** (**a**) i < iii < ii **EP 6.9** (**b**) 2.3×10^{-10} m **EP 6.10** (**d**) both (i) and (iii) **EP 6.11** (**c**) The electron moves in a circular orbit around the nucleus. **EP 6.12** (**d**) $n = 4, l = 3$ **EP 6.13** (**b**) both (i) and (ii) **EP 6.14** (**c**) 1, 2, 3 **EP 6.15** (**c**) both (i) and (iii) **EP 6.16** (**b**) *p* **EP 6.17** (**d**) electrons 2 and 3, which are degenerate and lower in energy than electron 1 **EP 6.18** (**d**) 10 **EP 6.19** (**b**) only Ca **EP 6.20** (**d**) $[Xe]6s^24f^{14}6d^6$

Chapter 7

EP 7.1 (**a**) 1+ **EP 7.2** (**c**) **1.86 Å** **EP 7.3** (**d**) O < N < P < Ge **EP 7.4** (**b**)F < Cl < S^{2-} < Se^{2-} **EP 7.5** (**a**) $Sr^{2+} < Rb^+ < Br^- < Se^{2-} < Te^{2-}$ **EP 7.6** (**e**) $Br^{2+}(g) \longrightarrow Br^{3+}(g) + e^-$ **EP 7.7** (**d**) Statements (ii) and (iii) are true **EP 7.8** (**a**) $[Kr]4d^4$ **EP 7.9** (**c**) it is likely to be a halogen **EP 7.10** (**d**) decreases, increases **EP 7.11** (**d**) If the nuclear charge of atom A is greater than that of atom B, then the effective nuclear charge of A is greater than that of B **EP 7.12** (**b**) increases, decreases **EP 7.13** (**d**) Si **EP 7.14** (**d**) Ag **EP 7.15** (**e**) $M(OH)_3(aq)$ **EP 7.16** (**c**) 3 **EP 7.17** (**e**) All three statements are true **EP 7.18** (**b**) S **EP 7.19** (**b**) The first ionization energy of cesium is less than that of sodium **EP 7.20** (**d**) $Sr^{2+}(aq) + H_2(g) + O_2(g)$; (**e**) $Sr^{2+}(aq) + OH^-(aq) + H_2(g)$

Chapter 8

EP 8.1 (**c**) Si **EP 8.2** (**e**) The attraction between cations and anions increases as the radii of the ions increase **EP 8.3** (**b**) ScN > MgO > NaCl > CsI **EP 8.4** (**b**) Ca **EP 8.5** (**c**) In forming the Cl—Cl bond, an electron is completely transferred from one Cl atom to the other **EP 8.6** (**b**) H_2S **EP 8.7** (**e**) All three statements are true **EP 8.8** (**b**) Fluorine has a large first ionization energy and a large electron affinity **EP 8.9** (**a**) H—F **EP 8.10** (**d**) 4.39 D **EP 8.11** (**d**) W is in a higher oxidation state in WF_6, which increases the degree of covalent bonding **EP 8.12** (**e**) more than one of a, b, c, d **EP 8.13** (**a**) 0 **EP 8.14** (**b**) 6 **EP 8.15** (**c**) 2 **EP 8.16** (**b**) Because of multiple resonance structures, the six carbon-carbon bonds in benzene, C_6H_6, all have the same length **EP 8.17** (**b**) NO_2^- and CO_3^{2-} **EP 8.18** (**c**) $:\!\underset{\cdot\cdot}{\ddot{F}}-\ddot{C}-\underset{\cdot\cdot}{\ddot{F}}\!:$ **EP 8.19** (**a**) SF_4 **EP 8.20** (**e**) 1, 2

Chapter 9

EP 9.1 (**c**) The shape of PF_3 can be obtained by removing one atom from a tetrahedral arrangement of atoms **EP 9.2** (**c**) 3 **EP 9.3** (**a**) H_2S has a trigonal planar electron-domain geometry **EP 9.4** (**d**) Statements ii and iii are true **EP 9.5** (**a**) 109.5° and 109.5° **EP 9.6** (**c**) Statements i and iii are true. **EP 9.7** (**b**) trigonal planar **EP 9.8** (**a**) The bond is formed from the overlap of a 3*p* orbital on one Cl atom with a 3*s* orbital on the other Cl atom **EP 9.9** (**b**) Hybrid orbitals can allow us to make multiple equivalent bonds when atomic orbitals can't do so **EP 9.10** (**c**) *sp*, 180 **EP 9.11** (**c**) O_3 **EP 9.12** (**c**) i and iii **EP 9.13** (**e**) 4, 4 **EP 9.14** (**d**) 8 **EP 9.15** (**d**) σ^*_{1s}, antibonding **EP 9.16** (**b**) H_2^+ and H_2^- **EP 9.17** (**a**) The number of molecular orbitals for a molecule is less than the number of atomic orbitals that are used to make them **EP 9.18** (**e**) 1, ½ **EP 9.19** (**b**) Statements i and ii are true **EP 9.20** (**e**) O_2, paramagnetic **EP 9.21** (**e**) $F_2^- < C_2^{2+} < O_2^- < N_2^-$

Chapter 10

EP 10.1 (**b**) Gases are incompressible **EP 10.2** (**d**) 10.3 m **EP 10.3** (**b**) 95.6 mm **EP 10.4** (**d**) 1000 atm **EP 10.5** (**c**) (i) and (iii) **EP 10.6** (**c**) If you plot *V* versus 1/*P* for a fixed quantity of a gas at constant temperature, you will get a straight line with a positive slope **EP 10.7** (**a**) It doubles **EP 10.8** (**b**) 1.9 L **EP 10.9** (**c**) 1.4 L **EP 10.10** (**e**) 9.39×10^5 g **EP 10.11** (**b**) 27 psi

EP 10.12 (**c**) 0.76 L **EP 10.13** (**a**) 0.92 g/L **EP 10.14** (**c**) 44.1 g/mol **EP 10.15** (**d**) 0.47 atm **EP 10.16** (**d**) 4.9 atm **EP 10.17** (**b**) 0.33 **EP 10.18** (**b**) The C_3H_8 and CH_4 molecules have the same average kinetic energy **EP 10.19** (**b**) Gas molecules move in circles **EP 10.20** (**a**) four, will not change **EP 10.21** (**d**) 335 m/s **EP 10.22** (**d**) both (ii) and (iii) **EP 10.23** (**b**) 37.2% **EP 10.24** (**a**) Underestimate by 12.38 atm **EP 10.25** (**e**) (ii), (iii), and (iv)

Chapter 11

EP 11.1(**d**) fills the entire volume of the container it occupies **EP 11.2** (**b**) only (ii) **EP 11.3** (**a**) only (i) **EP 11.4** (**a**) only (i) **EP 11.5** (**a**) dimethyl sulfoxide CH_3 **EP 11.6** (**d**) hydrogen peroxide, H_2O_2 **EP 11.7** (**d**) ionic bonding, ion–dipole interactions **EP 11.8** (**c**) $H_2 < O_2 < H_2CO < H_2O < CaO$ **EP 11.9** (**c**) $CH_4 < Ar < Cl_2 < CH_3COOH$ **EP 11.10** (**b**) The ethylene glycol molecule can form more hydrogen bonds per molecule than 1-propanol **EP 11.11** (**c**) vapor pressure **EP 11.12** (**d**) U-shaped, stronger **EP 11.13** (**d**) endothermic, larger **EP 1.14** (**d**) heat of vaporization and specific heat of $H_2O(l)$ **EP 111.15** (**c**) its ability to assume the shape and volume of its container **EP 11.16** (**b**) its vapor pressure equals the pressure of the surrounding atmosphere **EP 11.17** (**d**) both (i) and (ii) **EP 11.18** (d) The piston is at a higher position than it was before the heat was added **EP 11.19** (**c**) The normal boiling point of substance A is higher than that of substance B **EP 11.20** (**c**) phenol C_6H_5OH **EP 11.21** (**a**) high temperature, high pressure **EP 1.22** (**a**) It sublimes at about −200 °C **EP 1.23** (**b**) solid < smectic A liquid crystal < nematic liquid crystal < liquid **EP 1.24** (**e**) rigid rod-shaped molecules

Chapter 12

EP 12.1 (**d**) covalent-network **EP 12.2** (**a**) only i **EP 12.3** (b) lattice = square, atoms per unit cell = 1 A + 2 B **EP 12.4** (**a**) primitive cubic **EP 12.5** (**d**) rhombohedral **EP 12.6** (b) Ir **EP 12.7** (**c**) 6 **EP 12.8** (c) 1.45 Å **EP 12.9** (**e**) 78.5% **EP 12.10** (**b**) Nonmetallic elements are typically present in both interstitial and substitutional alloys **EP 12.11** (**e**) the low melting points of metals at the very end of the transition series, like cadmium (Cd) and mercury (Hg) **EP 12.12** (**a**) Cs **EP 12.13** (**c**) Ni_3Sn **EP 12.14** (**d**) 2.39 g/cm^3 **EP 12.15** (**d**) neither i nor ii **EP 12.16** (**e**) The atoms in the crystal have a large number (8–12) of nearest neighbors. **EP 12.17** (**e**) In general, the more polar the bonds are in compound semiconductors, the smaller the band gap. **EP 12.18** (**c**) Si:Al

Chapter 13

EP 13.1(**a**) increases, increases **EP 13.2** (**b**) acetone (CH_3COCH_3) dissolved in H_2O **EP 13.3** (**a**) only (i) **EP 13.4** (**b**) $|\Delta H_{\text{solute}}| < |\Delta H_{\text{solvent}}| < |\Delta H_{\text{mix}}|$ **EP 13.5** (**d**) equal to, saturated **EP 13.6** (**c**) settle to the bottom without dissolving, leaving the concentration of the solution unchanged **EP 13.7** (**a**) benzene (C_6H_6) **EP 13.8** (**d**) both (i) and (ii) **EP 13.9** (**a**) argon, 0.26 **EP 13.10** (**c**) 0.057 mol/L **EP 13.11** (**b**) 230 ppb **EP 13.12** (**d**) 2.91% **EP 13.13** (**b**) 1.82×10^{-5} **EP 13.14** (**b**) 0.022 M **EP 13.15** (**e**) 34 m **EP 13.16** (b) The vapor pressure will be higher in the container with the glucose solution **EP 13.17** (**c**) 0.125 mol **EP 13.18** (**b**) 0.15 m NaCl **EP 13.19** (**d**) the solute–solute, solvent–solvent and solute–solvent interactions are all assumed to be the same strength **EP 13.20** (**b**) hypotonic, hemolysis **EP 13.21** (**b**) only (ii) **EP 13.22** (**d**) norfenefrine $(C_8H_{11}NO_2)$ **EP 13.23** (**e**) 8 **EP 13.24** (**d**) 199 kg **EP 13.25** (**e**) both (i) and (iii) **EP 13.26** (**d**) solid emulsion **EP 13.27** (**c**) both (i) and (ii)

Chapter 14

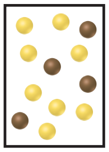
EP 14.1 (**d**) size of reaction vessel **EP 14.2** (**b**) Statements (i) and (ii) are true **EP 14.3** (**d**) $2.7 \times 10^{-5}\ M/s$ **EP 14.4** (**c**) $2\,A \longrightarrow B + 3\,C$ **EP 14.5** (**e**) None of statements i, ii, and iii is true **EP 14.6.** (**a**) $M^{-½}\,s^{-1}$ **EP 14.7** (**d**) does not change; increases by a factor of four **EP 14.8** (**c**) 4600 **EP 14.9** (**b**) Statements (i) and (ii) are true **EP 14.10** (**c**) 11 h **EP 14.11** (**a**) Only (ii) **EP 14.12** (**d**) $2.3 \times 10^{-1}\,s^{-1}$ **EP 14.13** (**c**) Statements (i) and (iii) are true **EP 14.14** (**e**) $A + B \longrightarrow X + Z$ **EP 14.15** (**a**) $C + C \longrightarrow K + Z$ **EP 14.16** (**c**) Rate $= k[P]^2[Q]$ **EP 14.17** (**c**) C **EP 14.18** (**d**) A catalyst cannot affect the mechanism of a reaction **EP 14.19** (**d**) The number of reactions per second done by her enzyme was 15 times that of the standard catalyst.

Chapter 15

EP 15.1 (**d**) i and ii **EP 15.2** (**c**) $K_c = \dfrac{[SO_3]^2}{[SO_2]^2[O_2]}$

EP 15.3 (**d**) 1.88×10^3

EP 15.4 (**b**)



EP 15.5 (**d**) $Ni(CO)_4(g) \rightleftharpoons Ni(s) + 4\,CO(g)$ **EP 15.6** (**d**) Statements ii and iii are true **EP 15.7** (**d**) 1.8×10^2 **EP 15.8** (e) Neither $[Ag^+]$ nor $[Cl^-]$ will change **EP 15.9** (**d**) increasing the volume of the vessel **EP 15.10** (a) 0.0410 **EP 15.11** (**d**) 1.4 **EP 15.12** (**b**) 4.7×10^{-2} **EP 15.13** (**c**) Statements i and ii are true **EP 15.14** (**b**) 0.36 atm **EP 15.15** (**a**) 0.57 atm **EP 15.16** (**d**) increase, decrease, leave unchanged **EP 15.17** (**a**) increasing the volume of the reaction vessel **EP 15.18** (**b**) The equilibrium will not shift **EP 15.19** (**c**) At a fixed temperature, a catalyst can shift the equilibrium toward the creation of more products

Chapter 16

EP 16.1(**b**) acceptor, donor **EP 16.2** (**b**) HSO_4^- and H_2O **EP 16.3** (**a**) Arrhenius **EP 16.4** (**d**) All three statements are true. **EP 16.5** (**c**) i and iii **EP 16.6** (**b**) O^{2-} **EP 16.7** (**e**) iii < ii < i **EP 16.8** (**c**) $2.5 \times 10^{-7}\ M$ **EP 16.9** (**a**) $1.0 \times 10^{-8}\ M$ **EP 16.10** (**d**) less than 7, equal to **EP 16.11** (**d**) 11.83 **EP 16.12** (**d**) less than, 3.47 **EP 16.13** (**c**) iii < i < ii **EP 16.14** (**c**) 12.48 **EP 16.15** (**e**) iii < ii < i **EP 16.16** (**b**) B < C < A **EP 16.17** (**c**) 6.7×10^{-5} **EP 16.18** (**e**) 9.0% **EP 16.19** (**a**) 2.30 **EP 16.20** (**e**) 2.64 **EP16.21** (**c**) **EP 16.22** (b) 2.32 **EP 16.23** (**a**) 0.012 **EP 16.24** (**c**) 9.52 **EP 16.25** (**d**) aniline and sulfite ion **EP 16.26** (**c**) 6.3×10^{-5} **EP 16.27** (**a**) 0.38 **EP 16.28** (**b**) weakest acid $HClO < C_5H_5NH^+ < CH_2ClCOOH$ strongest acid **EP 16.29** (**a**) weakest base $HCOO^- < BrO^- < (CH_3)_3N$ strongest base **EP 16.30** (**e**) iii < ii < i **EP 16.31** (b) $NaHSO_4$ and NaH_2PO_4 **EP 16.32** (**b**) $HOI < HIO_2 < HBrO_2 < HClO_2 < HClO_3$

Chapter 17

EP 17.1 (**d**) If you add the soluble salt KA to a solution of HA that is at equilibrium, the pH would increase **EP 17.2** (**e**) $1.73 \times 10^{-4}\ M$ **EP 17.3** (**c**) The acid and base concentrations must be equal **EP 17.4** (**a**) 0.174 **EP 17.5** (**a**) 60.7 g **EP 17.6** (**c**) C **EP 17.7** (**c**) The pH at the equivalence point is 7.00 **EP 17.8** (**d**) less than 7, NH_4^+ **EP 17.9** (**d**) The conjugate base that is formed at the equivalence point reacts with water **EP 17.10** (**c**) 1.60 **EP 17.11** (**c**) $[Ag^+]^3[PO_4^{3-}]$ **EP 17.12** (**e**) 1.40×10^{-37} **EP 17.13** (**b**) cobalt(II) hydroxide, $K_{sp} = 1.3 \times 10^{-15}$ **EP 17.14** (**d**) Raising the temperature of the solution **EP 17.15** (**e**) none of these actions **EP 17.16** (**c**) The precipitate was chromium hydroxide, which then reacted with more hydroxide to produce a soluble complex ion, $Cr(OH)_4^-(aq)$ **EP 17.17** (**a**) larger, will **EP 17.18** (d) aluminum **EP 17.19** (d) 10.52

Chapter 18

EP 18.1 (**a**) troposphere **EP 18.2** (**d**) thermosphere **EP 18.3** (**b**) $O_2 > CO_2 > CH_4$ **EP 18.4** (**d**) 1×10^{13} molecules/cm^3 **EP 18.5** (**c**) 6.24 mm Hg **EP 18.6** (**a**) 620 nm **EP 18.7** (**b**) −146 kJ/mol **EP 18.8** (**b**) catalyst, intermediate, product **EP 18.9** (**e**) 5.6, $CO_2(g) + H_2O(l) \longrightarrow H_2CO_3(aq)$ **EP 18.10** (**c**) O_3

EP 18.11 (**b**) 5.7 kg **EP 18.12** (**b**) only ii **EP 18.13** (**c**) They contain more than two atoms. **EP 18.14** (**c**) endothermic, exothermic **EP 18.15** (**a**) calcium oxide **EP 18.16** (**c**) both N and P **EP 18.17** (**b**) When $Al_2(SO_4)_3$ is added, it reacts with a variety of cations to form sulfate precipitates. These precipitates settle slowly, carrying suspended particles down with them. **EP 18.18** (**c**) All waste should be carefully disposed of after it has been created. **EP 18.19** (**d**) both ii and iii

Chapter 19

EP 19.1 (**d**) Equilibrium is achieved in a closed system when the rate of iron oxidation is equal to the rate of iron(III) oxide reduction. **EP 19.2** (**c**) i and iii **EP 19.3** (**d**) The value of ΔS for a system depends on the path taken between two states of the system. **EP 19.4** (**a**) Yes, because the heat transferred from the system has a negative sign. **EP 19.5** (**e**) All three statements are true. **EP 19.6** (**e**) one, two, less than **EP 19.7** (**c**) i and iii **EP 19.8** (**b**) 1 mol of $H_2(g)$ at 100 °C and 0.5 atm **EP 19.9** (**c**) At $T = 0$ K, a pure crystalline solid has zero possible microstates. **EP 19.10** (**d**) Standard molar entropies can have positive and negative values. **EP 19.11** (**a**) 326.4 J/K **EP 19.12** (**c**) All spontaneous reactions have a negative free-energy change. **EP 19.13** (**b**) −192.7 kJ **EP 19.14** (**a**) The reaction is spontaneous at all temperatures **EP 19.15** (**d**) 193 °C **EP 19.16** (**c**) +34,000 J **EP 19.17** (**e**) +2.2 kJ **EP 19.18** (**e**) +265 kJ/mol **EP 19.19** (**d**) $K = 23.2$

Chapter 20

EP 20.1 (**c**) HNO_3 **EP 20.2** (e) both ii and iii **EP 20.3** (**a**) $Br^-(aq)$ **EP 20.4** (**c**) only iii. **EP 20.5** (**d**) seven on the product side **EP 20.6** (**a**) one on the reactant side **EP 20.7** (**b**) The electrode is gaining mass and cations from the salt bridge are flowing into the half-cell. **EP 20.8** (**b**) oxidation, anode **EP 20.9** (**a**) −0.35 V **EP 20.10** (**c**) +1.08 V **EP 20.11** (**d**) cells 1 and 2 **EP 20.12** (**b**) $Cl_2(g)$ **EP 20.13** (**d**) Cl_2 and Br_2 **EP 20.14** (**d**) both ii and iii **EP 20.15** (**d**) −0.13 V **EP 20.16** (**d**) 2.5×10^4 **EP 20.17** (**b**) 0.55 V **EP 20.18** (**c**) 4.1×10^{-2} M **EP 20.19** (**c**) 0.46 V, cathode **EP 20.20** (**c**) As the battery discharges, K^+ migrate toward the anode and OH^- migrate toward the cathode to maintain charge balance. **EP 20.21** (**c**) It allows H^+ ions to migrate from the anode to the cathode. **EP 20.22** (**b**) An increase in the pH. **EP 20.23** (**c**) Water is reduced to H_2 gas at the cathode more easily than Na^+ ions are reduced to sodium metal. **EP 20.24** (**c**) 62 min

Chapter 21

EP 21.1 (**b**) uranium-234 **EP 21.2** (**b**) Statements i and ii are true. **EP 21.3** (**a**) alpha decay followed by beta emission **EP 21.4** (**d**) manganese-55 **EP 21.5** (**b**) $^{134}_{55}Cs$ **EP 21.6** (**d**) iodine-131 **EP 21.7** (**e**) $^{239}_{93}Np$ **EP 21.8** (**b**) 6.0 h **EP 21.9** (**d**) 45.5 yr **EP 21.10** (**c**) 2340 yr **EP 21.11** (**a**) 2.27×10^6 kJ **EP 21.12** (**c**) $3.19553534 \times 10^{-11}$ J **EP 21.13** (**a**) $^{144}_{54}Xe$ **EP 21.14** (**e**) All three statements are true.

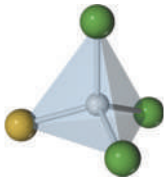
Chapter 22

EP 22.1 (**d**) Oxygen is better able to form π bonds than sulfur **EP 22.2** (**d**) C_2H_2 **EP 22.3** (**d**) +1 **EP 22.4** (**a**) F **EP 22.5** (**a**) 2 **EP 22.6** (**b**) carbon monoxide **EP 22.7** (**d**) Pd **EP 22. 8** (**b**) CuH **EP 22.9** (**a**) $Ni^{2+}(aq) + H_2(g) + SO_4^{2-}(aq)$ **EP 22.10** (**c**) Statements i and iii are true **EP 22.10** (**c**) trigonal bipyramidal, T-shaped **EP 22.12** (**c**) $HBrO_3$ **EP 22.13** (**a**) F_2 **EP 22.14** (**c**) HIO_3 **EP 22.15** (**c**) P_4O_{10} **EP 22.16** (**d**) bent **EP 22.17** (**d**) +6, +3 **EP 22.18** (**b**) $N_2H_4(aq) + O_2(aq) \longrightarrow N_2(g) + 2\,H_2O(l)$ **EP 22.19** (**e**) None of the statements is true **EP 22.20** (**c**) H_3PO_3 **EP 22.21** (**a**) SiC **EP 22.22** (**e**) +4 **EP 22.23** (**c**) sheets of linked SiO_4 tetrahedra **EP 22.24** (**c**) $Be_3Al_2Si_6O_{18}$ **EP. 22.25** (**e**) silicones, quartz, silicates

Chapter 23

EP 23.1 (**c**) niobium **EP 23.2** (**c**) $Rb_3[MoO_3F_3]$ **EP 23.3** (**b**) $[Kr]4d^6$ **EP 23.4** (**d**) ferromagnetism **EP 23.5** (**e**) $[Rh(NH_3)_4Cl_2]Cl$ **EP 23.6** (**c**) Statements i and iii are true. **EP 23.7** (**a**) Bipyridine is a monodentate ligand. **EP 23.8** (**e**) oxalate ion **EP 23.9** (**c**) tetraamminedichlororhodium(III) chloride **EP 23.10** (**b**) $Na_2[Pt(CN)_4]$

EP 23.11 (**a**)



$[MX_3Y]$

EP 23.12 (**d**) tetrahedral $[Co(NH_3)BrClI]^-$ **EP 23.13** (**d**) orange **EP 23.14** (**d**) Statements ii and iii are true. **EP 23.15** (**a**) t_2 set of orbitals, e set of orbitals **EP 23.16** (**c**) $X < H_2O < Y$ **EP 23.17** (**e**) i, ii, and iii **EP 23.18** (**d**) $[RhCl_6]^{3-}$ **EP 23.19** (**e**) 5 **EP 23.20** (**a**) octahedral, tetrahedral, square planar

Chapter 24

EP 24.1 (**e**) slightly greater than 120° **EP 24.2** (**c**) 3 **EP 24.3** (**b**) *cis*-2-butane **EP 24.4** (**e**) 20 **EP 24.5** (**b**) They are structural isomers **EP 24.6** (**b**) aromatic hydrocarbon, C_6H_4ClOH **EP 24.7** (**b**) only ii **EP 24.8** (**d**) 2-methylpropane **EP 24.9** (**c**) both i and ii **EP 24.10** (**c**) amine, carboxylic acid **EP 24.11** (**c**) a carboxylic acid, alcohol **EP 24.12** (**a**) 1 **EP 24.13** (**d**) 6 **EP 24.14** (**e**) The —R group contains only carbon and hydrogen, but the number of atoms in this group differs from one amino acid to another **EP 24.15** (**d**) Neither the α-helical structure nor the β-sheet structure will be retained **EP 24.16** (**b**) only ii **EP 24.17** (**d**) 3 **EP 24.18** (**b**) The two molecules are geometric isomers **EP 24.19** (**c**) condensation **EP 24.20** (**c**) both i and iii **EP 24.21** (**d**) lipids **EP 24.22** (**a**) adenine **EP 24.23** (**d**) 3′–CTGGAAT–5′ **EP 24.24** (**b**) DNAs and RNAs are built from the same nitrogen containing bases

GLOSSARY

absolute zero The temperature at which all thermal motion ceases: 0 K on the Kelvin scale and $-273.15\ ^\circ\text{C}$ on the Celsius scale.

absorption spectrum A pattern of variation in the amount of light absorbed by a sample as a function of wavelength.

accuracy A measure of how closely individual measurements agree with the correct, or "true," value.

acid A substance that is able to donate a H^+ ion (a proton) and, hence, increases the concentration of $H^+(aq)$ when it dissolves in water.

acid-dissociation constant (K_a) An equilibrium constant that expresses the extent to which an acid transfers a proton to solvent water.

acidic anhydride (acidic oxide) An oxide that forms an acid when added to water; soluble nonmetal oxides are acidic anhydrides.

acidic oxide (acidic anhydride) An oxide that reacts either with a base to form a salt or with water to form an acid.

acid rain Rainwater that has become excessively acidic because of absorption of pollutant oxides, notably SO_3, produced by human activities.

actinide element Element in which the 5*f* orbitals are only partially occupied.

activated complex (transition state) The particular arrangement of atoms found at the top of the potential-energy barrier as a reaction proceeds from reactants to products.

activation energy (E_a) The minimum energy needed for reaction; the height of the energy barrier to formation of products.

active site Specific site on a heterogeneous catalyst or an enzyme where catalysis occurs.

activity The decay rate of a radioactive material, generally expressed as the number of disintegrations per unit time.

activity series A list of metals in order of decreasing ease of oxidation.

addition polymerization Polymerization in which monomers are coupled through their multiple bonds.

addition reaction A reaction in which a reagent adds to the two carbon atoms of a carbon–carbon multiple bond.

adsorption The binding of molecules to a surface.

alcohol An organic compound obtained by substituting a hydroxyl group ($-OH$) for a hydrogen on a hydrocarbon.

aldehyde An organic compound that contains a carbonyl group ($C{=}O$) to which at least one hydrogen atom is attached.

alkali metals Members of group 1A in the periodic table.

alkaline earth metals Members of group 2A in the periodic table.

alkanes Compounds of carbon and hydrogen containing only carbon–carbon single bonds.

alkenes Hydrocarbons containing one or more carbon–carbon double bonds.

alkyl group A group that is formed by removing a hydrogen atom from an alkane.

alkynes Hydrocarbons containing one or more carbon–carbon triple bonds.

alloy A substance that has the characteristic properties of a metal and contains more than one element. Often there is one principal metallic component, with other elements present in smaller amounts. Alloys may be homogeneous or heterogeneous.

alpha emission A type of radioactive decay in which an atomic nucleus emits an alpha particle and thereby transforms (or "decays") into an atom with a mass number 4 less and atomic number 2 less.

alpha (α) helix A protein structure in which the protein is coiled in the form of a helix with hydrogen bonds between $C{=}O$ and $N{-}H$ groups on adjacent turns.

alpha particles Particles that are identical to helium-4 nuclei, consisting of two protons and two neutrons, symbol ${}^4_2He$ or ${}^4_2\alpha$.

amide An organic compound that has an NR_2 group attached to a carbonyl, where R may be H or a hydrocarbon group.

amine A compound that has the general formula R_3N, where R may be H or a hydrocarbon group.

amino acid A carboxylic acid that contains an amino ($-NH_2$) group attached to the carbon atom adjacent to the carboxylic acid ($-COOH$) functional group.

amorphous solid A solid whose molecular arrangement lacks the order (regularly repeating long-range pattern) of a crystal.

amphiprotic Refers to the capacity of a substance to either add or lose a proton (H^+).

amphoteric oxides and hydroxides Oxides and hydroxides that are only slightly soluble in water but that dissolve in either acidic or basic solutions.

angstrom A common non-SI unit of length, denoted Å, that is used to measure atomic dimensions: $1\text{Å} = 10^{-10}$ m.

anion A negatively charged ion.

anode An electrode at which oxidation occurs.

antibonding molecular orbital A molecular orbital in which electron density is concentrated outside the region between the two nuclei of bonded atoms. Such orbitals, designated as σ^* or π^*, are less stable (of higher energy) than bonding molecular orbitals.

antiferromagnetism A form of magnetism in which unpaired electron spins on adjacent sites point in opposite directions and cancel each other's effects.

aqueous solution A solution in which water is the solvent.

aromatic hydrocarbons Hydrocarbon compounds that contain a planar, cyclic arrangement of carbon atoms linked by both σ and delocalized π bonds.

Arrhenius equation An equation that relates the rate constant for a reaction to the frequency factor, A, the activation energy, E_a, and the temperature, T: $k = Ae^{-E_a/RT}$. In its logarithmic form it is written $\ln k = -E_a/RT + \ln A$.

atmosphere (atm) A unit of pressure equal to 760 torr; 1 atm = 101.325 kPa.

atom The smallest representative particle of an element. The almost infinitesimally small building blocks of matter.

atomic mass unit (amu) A unit based on the value of exactly 12 amu for the mass of the isotope of carbon that has six protons and six neutrons in the nucleus; 1 amu $= 1.66054 \times 10^{-24}$ g.

atomic number The number of protons in the nucleus of an atom of an element.

atomic radius An estimate of the size of an atom. See bonding atomic radius.

atomic weight The average mass of the atoms of an element in atomic mass units (amu); it is numerically equal to the mass in grams of one mole of the element.

autoionization The process whereby water spontaneously forms low concentrations of $H^+(aq)$ and $OH^-(aq)$ ions by proton transfer from one water molecule to another.

Avogadro's hypothesis A statement that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules.

Avogadro's law A statement that the volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas.

Avogadro's number (N_A) The number of ^{12}C atoms in exactly 12 g of ^{12}C; it equals 6.022×10^{23} mol^{-1}.

ball-and-stick model Model that depicts atoms as spheres and bonds as sticks.

band An array of closely spaced molecular orbitals occupying a continuous range of energy.

band gap The energy gap between a fully occupied valence band and an empty conduction band.

band structure The electronic structure of a bulk solid.

bar A unit of pressure equal to 10^5 Pa.

base A substance that is an H^+ acceptor; a base produces an excess of $OH^-(aq)$ ions when it dissolves in water.

base-dissociation constant (K_b) An equilibrium constant that expresses the extent to which a base reacts with solvent water, accepting a proton and forming $OH^-(aq)$.

basic anhydride (basic oxide) An oxide that forms a base when added to water; soluble metal oxides are basic anhydrides.

basic oxide (basic anhydride) An oxide that either reacts with water to form a base or reacts with an acid to form a salt and water.

battery A portable, self-contained electrochemical power source that contains one or more voltaic cells.

becquerel The SI unit of radioactivity. It corresponds to one nuclear disintegration per second.

Beer's law The light absorbed by a substance (A) equals the product of its extinction coefficient (ε), the path length through which the light passes (b), and the molar concentration of the substance (c): $A = \varepsilon bc$.

beta emission A nuclear decay process where a beta particle is emitted from the nucleus; also called beta decay.

beta particles Energetic electrons emitted from the nucleus, symbol $_{-1}^{0}e$ or β^-.

beta sheet A structural form of protein in which sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand.

bidentate ligand A ligand that contains two donor atoms, each with a nonbonding electron pair, that can coordinate to a metal.

bimolecular reaction An elementary reaction that involves two molecules.

biochemistry The study of the chemistry of living systems.

biodegradable Organic material that bacteria are able to oxidize.

biopolymers Three broad categories of polymers found in living organisms: proteins, polysaccharides (carbohydrates), and nucleic acids.

body-centered lattice A crystal lattice in which the lattice points are located at the center and corners of each unit cell.

bomb calorimeter A device for measuring the heat evolved in the combustion of a substance under constant-volume conditions.

bond angles The angles made by the lines joining the nuclei of the atoms in a molecule.

bond dipole The dipole moment that is due only to unequal electron sharing between two atoms in a covalent bond.

bond enthalpy The enthalpy change, ΔH, required to break a particular bond when the substance is in the gas phase.

bonding atomic radius The radius of an atom as defined by the distances separating it from other atoms to which it is chemically bonded.

bonding molecular orbital A molecular orbital in which the electron density is concentrated in the internuclear region. The energy of a bonding molecular orbital is lower than the energy of the separate atomic orbitals from which it forms.

bonding pair In a Lewis structure, a pair of electrons that is shared by two atoms.

bond length The distance between the centers of two bonded atoms.

bond order The number of bonding electron pairs shared between two atoms, minus the number of antibonding electron pairs: bond order = (number of bonding electrons − number of antibonding electrons)/2.

bond polarity A measure of the degree to which the electrons are shared unequally between two atoms in a chemical bond.

boranes Molecules containing only boron and hydrogen; covalent hydrides of boron.

Born–Haber cycle A thermodynamic cycle based on Hess's law that relates the lattice energy of an ionic substance to its enthalpy of formation and to other measurable quantities.

Boyle's law A law stating that at constant temperature, the product of the volume and pressure of a given amount of gas is a constant.

Brønsted–Lowry acid A substance (molecule or ion) that acts as a proton donor.

Brønsted–Lowry base A substance (molecule or ion) that acts as a proton acceptor.

Brownian motion The random motion of colloidal particles in solution due to collisions with solvent molecules.

buffer capacity The amount of acid or base a buffer can neutralize before the pH begins to change appreciably.

buffered solution (buffer) A solution that undergoes a limited change in pH upon addition of a small amount of acid or base.

calorie A unit of energy; it is the amount of energy needed to raise the temperature of 1 g of water by 1 °C from 14.5 °C to 15.5 °C. A related unit is the joule: 1 cal = 4.184 J.

calorimeter An apparatus that measures the heat released or absorbed in a chemical or physical process.

calorimetry The experimental measurement of heat produced in chemical and physical processes.

capillary action The process by which a liquid rises in a tube because of a combination of adhesion to the walls of the tube and cohesion between liquid particles.

carbide A binary compound of carbon with a metal or metalloid.

carbohydrates A class of substances formed from polyhydroxy aldehydes or ketones.

carbon black An amorphous form of carbon.

carbonyl group The $C{=}O$ double bond, a characteristic feature of several organic functional groups, such as ketones and aldehydes.

carboxylic acid An acid that contains the $-COOH$ functional group.

catalyst A substance that changes the speed of a chemical reaction without itself undergoing a permanent chemical change in the process.

cathode An electrode at which reduction occurs.

cathode rays Streams of electrons that are produced when a high voltage is applied to electrodes in an evacuated tube.

cathodic protection A means of protecting a metal against corrosion by making it the cathode in a voltaic cell. This can be achieved by attaching a more easily oxidized metal, which serves as an anode, to the metal to be protected.

cation A positively charged ion.

cell potential The potential difference between the cathode and anode in an electrochemical cell; it is measured in volts: $1\ \text{V} = 1\ \text{J/C}$. Also called electromotive force.

cellulose A polysaccharide of glucose; it is the major structural element in plant matter.

Celsius scale A temperature scale on which water freezes at 0° and boils at 100° at sea level.

chain reaction A series of reactions in which one reaction initiates the next.

changes of state Physical changes of matter from one state to a different one, for example, from a gas to a liquid.

charcoal An amorphous form of carbon produced when wood is heated strongly in a deficiency of air.

Charles's law A law stating that at constant pressure, the volume of a given quantity of gas is proportional to absolute temperature.

chelate effect The generally larger formation constants for bidentate and polydentate ligands as compared with the corresponding *monodentate* ligands.

chelating agent Bidentate and polydentate ligands capable of occupying two or more sites in the coordination sphere.

chemical bond A strong attractive force that exists between atoms in a molecule.

chemical changes Processes in which a substance is transformed into a chemically different substance; also called chemical reactions.

chemical equation A representation of a chemical reaction using the chemical formulas of the reactants and products; a balanced chemical equation contains equal numbers of atoms of each element on both sides of the equation.

chemical equilibrium A state of dynamic balance in which the rate of formation of the products of a reaction from the reactants equals the rate of formation of the reactants from the products; at equilibrium the concentrations of the reactants and products remain constant.

chemical formula A notation that uses chemical symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance.

chemical kinetics The area of chemistry concerned with the speeds, or rates, at which chemical reactions occur.

chemical nomenclature The rules used in naming substances.

chemical properties Properties that describe the way a substance may change, or *react*, to form other substances.

chemical reactions Processes in which a substance is transformed into a chemically different substance; also called chemical changes.

chemistry The scientific discipline that studies matter, its properties, and the changes that matter undergoes.

chiral A term describing a molecule or an ion that cannot be superimposed on its mirror image.

chlorofluorocarbons Ozone-damaging substances, principally $CFCl_3$ and CF_2Cl_2, that were once widely used as propellants in spray cans. They do not occur in nature.

chlorophyll A plant pigment that plays a major role in conversion of solar energy to chemical energy in photosynthesis.

cholesteric liquid crystal A liquid crystal having molecules arranged in layers, with their long axes parallel to the other molecules within the same layer. Moving from one layer to the next, the orientation of the molecules rotates by a fixed angle, resulting in a spiral pattern.

coal A naturally occurring solid containing hydrocarbons of high molecular weight, as well as compounds containing sulfur, oxygen, and nitrogen.

colligative property A property of a solvent (vapor-pressure lowering, freezing-point lowering, boiling-point elevation, osmotic pressure) that depends on the total concentration of solute particles present.

collision model A model of reaction rates based on the idea that molecules must collide to react; it explains the factors influencing reaction rates in terms of the frequency of collisions, the number of collisions with energies exceeding the activation energy, and the probability that the collisions occur with suitable orientations.

colloids (colloidal dispersions) Mixtures containing particles larger than normal solutes but small enough to remain suspended in the dispersing medium.

combination reaction A chemical reaction in which two or more substances combine to form a single product.

combustion reaction A chemical reaction that proceeds with evolution of heat and usually also a flame; most combustion involves reaction with oxygen, as in the burning of a match.

common-ion effect A shift of an equilibrium induced by an ion common to the equilibrium. Whenever a weak electrolyte and a strong electrolyte containing a common ion are together in solution, the weak electrolyte ionizes less than it would if it were alone in solution.

complementary colors Colors that, when mixed in proper proportions, appear white or colorless. For example, orange and blue are complementary colors that form white light when mixed; when blue is removed, the light looks orange.

complete ionic equation A chemical equation in which dissolved strong electrolytes (such as dissolved ionic compounds) are written as separate ions.

complex ion (complex) An assembly of a metal ion and the Lewis bases bonded to it.

compound A substance composed of two or more elements united chemically in definite proportions.

concentration The quantity of solute present in a given quantity of solvent or solution.

concentration cell A voltaic cell containing the same electrolyte and the same electrode materials in both the anode and cathode compartments. The emf of the cell is derived from a difference in the concentrations of the same electrolyte solutions in the compartments.

condensation polymerization Polymerization in which two molecules are joined to form a larger molecule by elimination of a small molecule, such as H_2O.

condensation reaction A reaction in which two molecules are joined to form a larger molecule by elimination of a small molecule, such as H_2O.

conduction band A band of unoccupied antibonding molecular orbitals lying higher in energy than the occupied valence band and distinctly separated from it.

conjugate acid A substance formed by addition of a proton to a Brønsted–Lowry base.

conjugate acid–base pair An acid and a base, such as H_2O and OH^-, that differ only in the presence or absence of a proton.

conjugate base A substance formed by the loss of a proton from a Brønsted–Lowry acid.

continuous spectrum A spectrum that contains radiation distributed over all wavelengths.

conversion factor A fraction whose numerator and denominator are the same quantity expressed in different units.

coordination compound A compound containing a coordination complex.

coordination number The number of adjacent atoms in a crystal structure to which an atom is directly bonded. In a complex, the coordination number of the metal ion is the number of atoms bonded to the metal ion.

coordination sphere The central metal ion and its surrounding ligands.

coordination-sphere isomers Structural isomers that differ in which species in the complex are ligands and which are outside the coordination sphere in the solid.

copolymer A complex polymer resulting from the polymerization of two or more chemically different monomers.

core electrons The electrons that are not in the outermost shell of an atom.

corrosion Spontaneous redox reactions in which a metal is oxidized by some substance in its environment and converted to an unwanted compound.

covalent bond A bond formed between two or more atoms by a sharing of electrons.

covalent-network solids Solids that are held together by an extended network of covalent bonds.

critical mass The amount of fissionable material necessary to maintain a nuclear chain reaction.

critical point The temperature and pressure beyond which the liquid and gas phases are indistinguishable from each other.

critical pressure The pressure at which a gas at its critical temperature is converted to a liquid state.

critical temperature The highest temperature at which a distinct liquid phase can form. The critical temperature increases with an increase in the magnitude of intermolecular forces.

cross-linking A method of stiffening polymers by introducing chemical bonds between chains.

crystal-field theory A theory that accounts for the colors and the magnetic and other properties of transition-metal complexes in terms of the splitting of the energies of metal ion *d* orbitals by the electrostatic interaction with the ligands.

crystal lattice The geometrical pattern of points on which the unit cells are arranged; in effect, an abstract (that is, not real) scaffolding for the crystal structure.

crystalline solid (crystal) A solid whose internal arrangement of atoms, molecules, or ions possesses a regularly repeating pattern throughout the solid.

crystallinity A measure of the extent to which a solid maintains the regular repeating pattern of atoms seen in a crystalline solid.

crystallization The process in which molecules, ions, or atoms come together to form a crystalline solid. The opposite of a solid dissolving in a solvent to form a solution.

cubic close packing A crystal structure where the atoms are packed together as close as possible, and the close-packed layers of atoms adopt a three-layer repeating pattern that leads to a face-centered cubic unit cell.

curie A measure of radioactivity: 1 curie $= 3.7 \times 10^{10}$ nuclear disintegrations per second.

cycloalkanes Saturated hydrocarbons of general formula C_nH_{2n} in which the carbon atoms form a closed ring.

Dalton's law of partial pressures A law stating that the total pressure of a mixture of gases is the sum of the pressures that each gas would exert if it were present alone.

***d*–*d* transition** The transition of an electron in a transition-metal compound from a lower-energy *d* orbital to a higher-energy *d* orbital.

decomposition reaction A chemical reaction in which a single compound reacts to give two or more products.

degenerate A situation in which two or more orbitals have the same energy.

delocalized electrons Electrons that are spread over a number of atoms in a molecule or a crystal rather than localized on a single atom or a pair of atoms.

density The amount of mass in a unit volume of a substance.

deoxyribonucleic acid (DNA) A polynucleotide in which the sugar component is deoxyribose.

derived unit An SI unit obtained by multiplication or division of one or more of the SI base units.

desalination The removal of salts from seawater, brine, or brackish water to make it fit for human consumption.

deuterium The isotope of hydrogen whose nucleus contains a proton and a neutron: $^{2}_{1}H$.

dextrorotatory, or merely dextro or *d* A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the right (clockwise).

diamagnetism A type of magnetism that causes a substance with no unpaired electrons to be weakly repelled from a magnetic field.

diatomic molecule A molecule composed of only two atoms.

diffusion The spreading of one substance throughout a space or throughout a second substance.

dilution The process of preparing a less concentrated solution from a more concentrated one by adding solvent.

dimensional analysis A method of problem solving in which units are multiplied together or divided into each other along with the numerical values. Dimensional analysis ensures that the final answer of a calculation has the desired units.

dipole A molecule with one end having a partial negative charge and the other end having a partial positive charge.

dipole–dipole interactions A force that becomes significant when polar molecules come in close contact with one another. The force is attractive when the positive end of one polar molecule approaches the negative end of another.

dipole moment A measure of the separation and magnitude of the positive and negative charges in polar molecules.

disaccharide Two monosaccharide units linked together by a condensation reaction.

dispersion forces Intermolecular forces resulting from attractions between induced dipoles. Also called London dispersion forces.

displacement reaction A reaction in which an ion in solution is displaced (replaced) through oxidation of an element.

disproportionation reaction A reaction in which an element is simultaneously oxidized and reduced.

distillation A separation process that depends on the different boiling points of substances.

donor atom The atom of a ligand that bonds to the central metal ion in a coordination complex.

doping The process of adding controlled amounts of impurity atoms to a material. For example, incorporation of P into Si.

double bond A covalent bond involving two electron pairs.

double helix The structure for DNA that involves the winding of two DNA polynucleotide chains together in a helical arrangement. The two strands of the double helix are complementary in that the organic bases on the two strands are paired for optimal hydrogen bond interaction.

dynamic equilibrium A state of balance in which opposing processes occur at the same rate.

effective nuclear charge The net positive charge experienced by an electron in a many-electron atom; this charge is not the full nuclear charge because there is some shielding of the nucleus by the other electrons in the atom.

effusion The escape of a gas through an orifice or hole.

elastomer A material that can undergo a substantial change in shape via stretching, bending, or compression and return to its original shape upon release of the distorting force.

electrochemistry The branch of chemistry that deals with the relationships between electricity and chemical reactions.

electrolysis reaction A reaction in which a nonspontaneous redox reaction is brought about by the passage of current under a sufficient external electrical potential. The devices in which electrolysis reactions occur are called electrolytic cells.

electrolyte A solute that produces ions in solution; an electrolytic solution conducts an electric current.

electrolytic cell A device in which a nonspontaneous oxidation–reduction reaction is caused to occur by passage of current under a sufficient external electrical potential.

electromagnetic radiation (radiant energy) A form of energy that has wave characteristics and that propagates through a vacuum at the characteristic speed of 3.00×10^8 m/s.

electrometallurgy The use of electrolysis to reduce or refine metals.

electromotive force (emf) A measure of the driving force, or *electrical pressure*, for the completion of an electrochemical reaction. Electromotive force is measured in volts: $1 \text{ V} = 1 \text{ J/C}$. Also called the cell potential.

electron A negatively charged subatomic particle found outside the atomic nucleus; it is a part of all atoms.

electron affinity The energy change that occurs when an electron is added to a gaseous atom or ion.

electron capture A mode of radioactive decay in which an inner-shell orbital electron is captured by the nucleus.

electron configuration The arrangement of electrons in the orbitals of an atom or molecule

electron density The probability of finding an electron at any particular point in an atom; this probability is equal to ψ^2, the square of the wave function. Also called the probability density.

electron domain In the VSEPR model, a region about a central atom in which an electron pair is concentrated.

electron-domain geometry The three-dimensional arrangement of the electron domains around an atom according to the VSEPR model.

electronegativity A measure of the ability of an atom that is bonded to another atom to attract electrons to itself.

electronic charge The negative charge carried by an electron; it has a magnitude of 1.602×10^{-19} C.

electronic structure The arrangement of electrons in an atom or molecule.

electron-sea model A model for the behavior of electrons in metals.

electron shell A collection of orbitals that have the same value of n. For example, the orbitals with $n = 3$ (the $3s$, $3p$, and $3d$ orbitals) comprise the third shell.

electron spin A property of the electron that makes it behave as though it were a tiny magnet. The electron behaves as if it were spinning on its axis; electron spin is quantized.

element A substance that cannot be decomposed into simpler substances.

elemental composition The percentage composition of an element in a substance.

elementary reaction A process in a chemical reaction that occurs in a single step. An overall chemical reaction consists of one or more elementary reactions or steps.

empirical formula A chemical formula that shows the kinds of atoms and their relative numbers in a substance in the smallest possible whole-number ratios.

enantiomers Molecules of a chiral substance that are nonsuperimpoable mirror images of each other.

endothermic process A process in which a system absorbs heat from its surroundings.

energy The capacity to do work or to transfer heat.

energy-level diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived. Also called a **molecular-orbital diagram**.

enthalpy A quantity defined by the relationship $H = E + PV$; the enthalpy change, ΔH, for a reaction that occurs at constant pressure is the heat evolved or absorbed in the reaction: $\Delta H = q_p$.

enthalpy of formation The enthalpy change that accompanies the formation of a substance from the most stable forms of its component elements.

enthalpy of reaction The enthalpy change associated with a chemical reaction.

entropy A measure of the degree of *randomness* or *disorder* associated with a system.

enzyme A protein molecule that acts to catalyze specific biochemical reactions.

equilibrium constant The numerical value of the equilibrium-constant expression for a system at equilibrium. The equilibrium constant is usually denoted by K_p for gas-phase systems or K_c for solution-phase systems.

equilibrium-constant expression The expression that describes the relationship between the activities (usually expressed as concentrations or partial pressures) of the substances present in a chemical reaction at equilibrium.

equivalence point The point in a titration at which the added solute reacts completely with the solute present in the solution.

ester An organic compound that has an –OR group attached to a carbonyl; it is the product of a reaction between a carboxylic acid and an alcohol.

ether A compound in which two hydrocarbon groups are bonded to one oxygen.

exchange (metathesis) reaction A reaction between compounds that when written as a molecular equation appears to involve the exchange of ions between the two reactants.

excited state A higher energy state than the ground state.

exothermic process A process in which a system releases heat to its surroundings.

extensive property A property that depends on the amount of sample considered; for example, mass or volume.

face-centered lattice A crystal lattice in which the lattice points are located at the faces and corners of each unit cell.

Faraday constant (*F*) The magnitude of charge of one mole of electrons: 96,485 C/mol.

***f*-block metals** Lanthanide and actinide elements in which the 4*f* or 5*f* orbitals are partially occupied.

ferrimagnetism A form of magnetism in which unpaired electron spins on different-type ions point in opposite directions but do not fully cancel out.

ferromagnetism A form of magnetism in which unpaired electron spins align parallel to one another.

first law of thermodynamics A statement that energy is conserved in any process. One way to express the law is that the change in internal energy, ΔE, of a system in any process is equal to the heat, q, added to the system, plus the work, w, done on the system by its surroundings: $\Delta E = q + w$.

first-order reaction A reaction in which the reaction rate is proportional to the concentration of a single reactant, raised to the first power.

fission The splitting of a large nucleus into two smaller ones.

folding The process by which a protein adopts its biologically active shape.

force A push or a pull.

formal charge The charge an atom (in a molecule) would have if each bonding electron pair in the molecule were shared equally between its two atoms.

formation constant The equilibrium constant for formation of a complex ion from the metal ion and Lewis bases (ligands) present in solution.

formula weight The sum of the atomic weights (AW) of the atoms in the chemical formula of the substance. For example, the formula weight of NO_2 (46.0 amu) is the sum of the masses of one nitrogen atom and two oxygen atoms.

fossil fuels Coal, oil, and natural gas, which are presently our major sources of energy.

fracking The practice in which water laden with sand and other materials is pumped at high pressure into rock formations to release natural gas and other petroleum materials.

free energy (Gibbs free energy, *G*) A thermodynamic state function that gives a criterion for spontaneous change in terms of enthalpy and entropy: $G = H - TS$.

free radical A substance with one or more unpaired electrons.

frequency The number of times per second that one complete wavelength passes a given point.

frequency factor (*A*) A term in the Arrhenius equation that is related to the frequency of collision and the probability that the collisions are favorably oriented for reaction.

fuel cell A voltaic cell that utilizes the oxidation of a conventional fuel, such as H_2 or CH_4, in the cell reaction.

fuel value The energy released when 1 g of a substance is combusted.

functional group An atom or group of atoms that imparts characteristic chemical properties to an organic compound.

fusion The joining of two light nuclei to form a more massive one.

galvanic cell See **voltaic (galvanic) cell**.

gamma radiation Energetic electromagnetic radiation emanating from the nucleus of a radioactive atom.

gas Matter that has no fixed volume or shape; it uniformly fills its container.

gas constant (*R*) The constant of proportionality in the ideal-gas equation.

geometric isomerism A form of isomerism in which compounds with the same type and number of atoms and the same chemical bonds have different spatial arrangements of these atoms and bonds.

Gibbs free energy A thermodynamic state function that combines enthalpy and entropy, in the form $G = H - TS$. For a change occurring at constant temperature and pressure, the change in free energy is $\Delta G = \Delta H - T\Delta S$.

glass An amorphous solid formed by fusion of SiO_2, CaO, and Na_2O. Other oxides may also be used to form glasses with differing characteristics.

glucose A polyhydroxy aldehyde whose formula is $CH_2OH(CHOH)_4CHO$; it is the most important of the monosaccharides.

glycogen The general name given to a group of polysaccharides of glucose that are synthesized in mammals and used to store energy from carbohydrates.

Graham's law A law stating that the rate of effusion of a gas is inversely proportional to the square root of its molecular weight.

gray (Gy) The SI unit for radiation dose corresponding to the absorption of 1 J of energy per kilogram of biological material; 1 Gy = 100 rads.

green chemistry Chemistry that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment.

greenhouse gases Gases in an atmosphere that absorb and emit infrared radiation (radiant heat), "trapping" heat in the atmosphere.

ground state The lowest-energy, or most stable, state.

group Elements that are in the same column of the periodic table; elements within the same group or family exhibit similarities in their chemical behavior.

Haber process The catalyst system and conditions of temperature and pressure developed by Fritz Haber and coworkers for the formation of NH_3 from H_2 and N_2.

half-life The time required for the concentration of a reactant substance to decrease to half its initial value; the time required for half of a sample of a particular radioisotope to decay.

half-reaction An equation for either an oxidation or a reduction that explicitly shows the electrons involved, for example, $Zn^{2+}(aq) + 2\,e^- \longrightarrow Zn(s)$.

halogens Members of group 7A in the periodic table.

heat The energy that causes the temperature of an object to increase. The flow of energy from a body at higher temperature to one at lower temperature when they are placed in thermal contact.

heat capacity The quantity of heat required to raise the temperature of a sample of matter by 1 °C (or 1 K).

heat of fusion The enthalpy change, ΔH, for melting a solid.

heat of sublimation The enthalpy change, ΔH, for vaporization of a solid.

heat of vaporization The enthalpy change, ΔH, for vaporization of a liquid.

Henderson–Hasselbalch equation The relationship among the pH, pK_a, and the concentrations of acid and conjugate base in an aqueous solution: $pH = pK_a + \log \frac{[\text{base}]}{[\text{acid}]}$.

Henry's law A law stating that the concentration of a gas in a solution, S_g, is proportional to the pressure of gas over the solution: $S_g = kP_g$.

Hess's law If a reaction is carried out in a series of steps, ΔH for the overall reaction equals the sum of the enthalpy changes for the individual steps.

heterogeneous alloy An alloy in which the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present.

heterogeneous catalyst A catalyst that is in a different phase from that of the reactant substances.

heterogeneous equilibrium The equilibrium established between substances in two or more different phases, for example, between a gas and a solid or between a solid and a liquid.

hexagonal close packing A crystal structure where the atoms are packed together as closely as possible. The close-packed layers adopt a two-layer repeating pattern, which leads to a primitive hexagonal unit cell.

high-spin complex A complex whose electrons are arranged to give the maximum number of unpaired electrons.

hole A vacancy in the valence band of a semiconductor, created by doping.

homogeneous catalyst A catalyst that is in the same phase as the reactant substances.

homogeneous equilibrium The equilibrium established between reactant and product substances that are all in the same phase.

Hund's rule A rule stating that electrons occupy degenerate orbitals in such a way as to maximize the number of electrons with the same spin. In other words, each orbital has one electron placed in it before pairing of electrons in orbitals occurs.

hybridization The mathematical mixing of different types of atomic orbitals to produce a set of equivalent hybrid orbitals.

hybrid orbital An orbital that results from the mixing of different kinds of atomic orbitals on the same atom. For example, an sp^3 hybrid results from the mixing, or hybridizing, of one *s* orbital and three *p* orbitals.

hydration Solvation when the solvent is water.

hydride ion An ion formed by the addition of an electron to a hydrogen atom: H^-.

hydrocarbons Compounds composed of only carbon and hydrogen.

hydrogen bonding Bonding that results from intermolecular attractions between molecules containing hydrogen bonded to an electronegative element. The most important examples involve OH, NH, and HF bonds.

hydrolysis A reaction with water. When a cation or anion reacts with water, it changes the pH.

hydronium ion (H_3O^+) The predominant form of the proton in aqueous solution.

hydrophilic Water attracting. The term is often used to describe a type of colloid.

hydrophobic Water repelling. The term is often used to describe a type of colloid.

hypervalent A compound with more than an octet of electrons around the central atom.

hypothesis A model or tentative explanation of a series of observations.

ideal gas A hypothetical gas whose pressure, volume, and temperature behavior is completely described by the ideal-gas equation.

ideal-gas equation An equation of state for gases that embodies Boyle's law, Charles's law, and Avogadro's hypothesis in the form $PV = nRT$.

ideal solution A solution where the solvent-solute, solute-solute, and solvent-solvent interactions are assumed to all be the same strength. An ideal solution perfectly obeys Raoult's Law.

immiscible liquids Liquids that do not dissolve in one another to a significant extent.

indicator A substance added to a solution that changes color when the added solute reacts with the solute present in solution. The most common type of indicator is an acid–base indicator whose color changes as a function of pH.

instantaneous rate The reaction rate at a particular time as opposed to the average rate over an interval of time.

insulators Materials that do not conduct electricity.

intensive property A property that does not depend on the amount of sample being examined, for example, density.

interhalogens Compounds formed between two different halogen elements. Examples include IBr and BrF_3.

intermediate A substance formed in one elementary step of a multistep mechanism and consumed in another; it is neither a reactant nor an ultimate product of the overall reaction.

intermetallic compound A homogeneous alloy with definite properties and a fixed composition.

intermolecular forces Forces that exist between molecules.

internal energy The sum of all the kinetic and potential energies of the components of the system. When a system undergoes a change, the change in internal energy, ΔE, is defined as the heat, q, added to the system, plus the work, w, done on the system by its surroundings: $\Delta E = q + w$.

interstitial alloy An alloy formed when solute atoms occupy interstitial positions in the "holes" between solvent atoms.

ion Electrically charged atom or group of atoms (polyatomic ion); ions can be positively or negatively charged, depending on whether electrons are lost (positive) or gained (negative) by the atoms.

ion–dipole force The force that exists between an ion and a polar molecule that possesses a permanent dipole moment.

ionic bond A bond formed by the electrostatic attractions between oppositely charged ions. The ions are formed from atoms by transfer of one or more electrons.

ionic compound A compound composed of cations and anions.

ionic hydrides Compounds formed when hydrogen reacts with alkali metals and also the heavier alkaline earths (Ca, Sr, and Ba); these compounds contain the hydride ion, H^-.

ionic solids Solids that are held together by the mutual electrostatic attraction between cations and anions.

ionization energy The minimum energy required to remove an electron from the ground state of an isolated gaseous atom or ion.

ionizing radiation Radiation that has sufficient energy to remove an electron from a molecule, thereby ionizing it.

ion-product constant For water, K_w is the product of the hydrogen ion and hydroxide ion concentrations: $[H^+][OH^-] = K_w = 1.0 \times 10^{-14}$ at 25 °C.

irreversible process A process that leaves the surroundings somehow changed when the system is restored to its original state.

isoelectronic series A series of atoms, ions, or molecules having the same number of electrons.

isomers Compounds whose molecules have the same overall composition but different structures.

isothermal process A process that occurs at constant temperature.

isotopes Atoms of the same element containing different numbers of neutrons and therefore having different masses.

joule (J) The SI unit of energy, 1 kg-m^2/s^2. A related unit is the calorie: $4.184\,J = 1$ cal.

Kelvin scale The SI temperature scale; the SI unit for temperature is the kelvin. Zero on the Kelvin scale corresponds to -273.15 °C.

ketone A compound in which the carbonyl group ($C{=}O$) occurs at the interior of a carbon chain and is therefore flanked by carbon atoms.

kinetic energy The energy that an object possesses by virtue of its motion.

kinetic-molecular theory of gases A set of assumptions about the nature of gases. These assumptions, when translated into mathematical form, yield the ideal-gas equation.

lanthanide contraction The gradual decrease in atomic and ionic radii with increasing atomic number among the lanthanide elements, atomic numbers 57 through 70. The decrease arises because of a gradual increase in effective nuclear charge through the lanthanide series.

lanthanide (rare earth) element Element in which the 4f subshell is only partially occupied.

lattice energy The energy required to separate completely the ions in an ionic solid into gaseous ions.

lattice points Points in a crystal, all of which have identical environments.

lattice vectors The vectors $\boldsymbol{a}$, $\boldsymbol{b}$, and $\boldsymbol{c}$ that define each lattice point in a crystal lattice. Beginning from any lattice point, it is possible to move to any other lattice point by adding together whole-number multiples of the two lattice vectors.

law of conservation of mass The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction.

law of constant composition A law that states that the elemental composition of a compound is always the same; also called the **law of definite proportions**.

law of definite proportions A law that states that the elemental composition of a substance is always the same; also called the **law of constant composition**.

law of mass action The rules by which the equilibrium constant is expressed in terms of the concentrations of reactants and products, in accordance with the balanced chemical equation for the reaction.

law of multiple proportions If two elements A and B combine to form more than one compound, the masses of B that can combine with a given mass of A are in the ratio of small whole numbers.

Le Châtelier's principle A principle stating that when we disturb a system at chemical equilibrium, the relative concentrations of reactants and products shift so as to partially undo the effects of the disturbance.

levorotatory, or merely levo or *l* A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the left (counterclockwise).

Lewis acid An electron-pair acceptor.

Lewis base An electron-pair donor.

Lewis structure A representation of covalent bonding in a molecule that is drawn using Lewis symbols. Shared electron pairs are shown as lines, and unshared electron pairs are shown as pairs of dots. Only the valence-shell electrons are shown.

Lewis symbol (electron-dot symbol) The chemical symbol for an element, with a dot for each valence electron.

ligand An ion or molecule that coordinates to a metal atom or to a metal ion to form a complex.

limiting reactant (limiting reagent) The reactant that is completely consumed in a reaction; the amount of product that can form is limited by the complete consumption of the limiting reactant.

line spectrum A spectrum that contains radiation at only certain specific wavelengths.

linkage isomers Structural isomers of coordination compounds in which a ligand is capable of coordinating to a metal in two ways.

lipid A nonpolar biological molecule used by organisms for long-term energy storage or as a structural component.

liquid Matter that has a distinct volume independent of its container.

liquid crystal A substance that exhibits a viscous, milky state between the liquid and solid states.

lock-and-key model A model of enzyme action in which the substrate molecule is pictured as fitting rather specifically into the active site on the enzyme. It is assumed that in being bound to the active site, the substrate is somehow activated for reaction.

low-spin complex A metal complex in which the electrons are paired in lower-energy orbitals.

macroporous Solids having pores that can be seen with an optical microscope.

magic numbers Numbers of protons and neutrons that result in very stable nuclei.

main-group elements Elements in the *s* and *p* blocks of the periodic table.

mass A measure of the amount of material in an object. In SI units, mass is measured in kilograms.

mass defect The difference between the mass of a nucleus and the total masses of the individual nucleons that it contains.

mass number The sum of the number of protons and neutrons in the nucleus of a particular atom.

mass percentage The number of grams of solute in each 100 g of solution.

mass spectrometer An instrument used to measure the precise masses and relative amounts of atomic and molecular ions.

matter Anything that occupies space and has mass; the physical material of the universe.

matter waves The term used to describe the wave characteristics of a moving particle.

mean free path The average distance traveled by a gas molecule between collisions.

mesoporous Solids having pore sizes in the range 2 to 50 nm.

metal complex Species that are assemblies of a central metal ion bonded to a group of surrounding molecules or ions, such as $[Ag(NH_3)_2]^+$ and $[Fe(H_2O)_6]^{3+}$.

metallic bond Bonding, usually in solid metals, in which the bonding electrons are delocalized and therefore, relatively free to move throughout the three-dimensional structure.

metallic character The extent to which an element exhibits the physical and chemical properties characteristic of metals, for example, luster, malleability, ductility, and good thermal and electrical conductivity.

metallic elements (metals) Elements that are usually solids at room temperature, exhibit high electrical and heat conductivity, and appear lustrous. Most of the elements in the periodic table are metals.

metallic hydrides Compounds formed when hydrogen reacts with metals; these compounds contain the hydride ion, H^-.

metallic solids Solids that are composed of metal atoms held together by a delocalized “sea” of collectively shared valence electrons.

metalloids Elements that lie along the diagonal line separating the metals from the nonmetals in the periodic table; the properties of metalloids are intermediate between those of metals and nonmetals.

metallurgy The science of extracting metals from their natural sources by a combination of chemical and physical processes. It is also concerned with the properties and structures of metals and alloys.

metathesis (exchange) reaction A reaction in which two substances react through an exchange of their component ions: $AX + BY \longrightarrow AY + BX$. Precipitation and acid–base neutralization reactions are examples of metathesis reactions.

metric system A system of measurement used in science and in most countries. The meter and the gram are examples of metric units.

microporous Refers to solids that have pores up to 2 nm in size.

microstate A single possible arrangement of the positions and kinetic energies of the molecules when the molecules are in a specific thermodynamic state.

mineral A solid, inorganic substance occurring in nature, such as calcium carbonate, which occurs as calcite.

miscible liquids Liquids that mix in all proportions.

mixture A combination of two or more substances in which each substance retains its own chemical identity.

molal boiling-point-elevation constant (K_b) A constant characteristic of a particular solvent that gives the increase in boiling point as a function of solution molality: $\Delta T_b = iK_b m$.

molal freezing-point-depression constant (K_f) A constant characteristic of a particular solvent that gives the decrease in freezing point as a function of solution molality: $\Delta T_f = -iK_f m$.

molality The concentration of a solution expressed as moles of solute per kilogram of solvent; abbreviated *m*.

molar heat capacity The heat required to raise the temperature of one mole of a substance by 1 °C.

molarity The concentration of a solution expressed as moles of solute per liter of solution; abbreviated *M*.

molar mass The mass of one mole of a substance in grams; it is numerically equal to the formula weight in atomic mass units.

mole A collection of Avogadro's number (6.022×10^{23}) of objects; for example, a mole of H_2O is 6.022×10^{23} H_2O molecules.

molecular compound A compound that consists of molecules.

molecular equation A chemical equation in which the formula for each substance is written without regard for whether it is an electrolyte or a nonelectrolyte.

molecular formula A chemical formula that indicates the actual number of atoms of each element in one molecule of a substance.

molecular geometry The arrangement in space of the atoms of a molecule.

molecular hydrides Compounds formed when hydrogen reacts with nonmetals and metalloids.

molecularity The number of molecules that participate as reactants in an elementary reaction.

molecular orbital (MO) An allowed state for an electron in a molecule. According to molecular-orbital theory, a molecular orbital is entirely analogous to an atomic orbital, which is an allowed state for an electron in an atom. Most bonding molecular orbitals can be classified as σ or π, depending on the disposition of electron density with respect to the internuclear axis.

molecular-orbital diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived; also called an **energy-level diagram**.

molecular-orbital theory A theory that accounts for the allowed states for electrons in molecules by using specific wave functions.

molecular solids Solids that are composed of molecules held together by their intermolecular forces.

molecular weight The sum of the atomic weights (AW) of the atoms represented by their chemical formula for a molecule.

molecule A chemical combination of two or more atoms.

mole fraction The ratio of the number of moles of one component of a mixture to the total moles of all components; abbreviated X, with a subscript to identify the component.

momentum The product of the mass, m, and velocity, v, of an object.

monodentate ligand A ligand that binds to the metal ion via a single donor atom. It occupies one position in the coordination sphere.

monomers Molecules with low molecular weights, which can be joined together (polymerized) to form a polymer.

monosaccharide A simple sugar, most commonly containing six carbon atoms. The joining together of monosaccharide units by condensation reactions results in formation of polysaccharides.

motif In a crystal, the group of atoms associated with each lattice point.

nanomaterial A solid whose dimensions range from 1 to 100 nm and whose properties differ from those of a bulk material with the same composition.

natural gas A naturally occurring mixture of gaseous hydrocarbon compounds composed of hydrogen and carbon.

nematic liquid crystalline phase A liquid crystal in which the molecules are aligned in the same general direction, along their long axes, but in which the ends of the molecules are not aligned.

Nernst equation An equation that relates the cell emf, E, to the standard emf, $E°$, and the reaction quotient, Q: $E = E° - (RT/nF) \ln Q$.

net ionic equation A chemical equation for a solution reaction in which soluble strong electrolytes are written as ions and spectator ions are omitted.

neutralization reaction A reaction in which an acid and a base react in stoichiometrically equivalent amounts; the neutralization reaction between an acid and a metal hydroxide produces water and a salt.

neutron An electrically neutral particle found in the nucleus of an atom; it has approximately the same mass as a proton.

noble gases Members of group 8A in the periodic table.

nodal plane A plane where the electron density in an atom or a molecule is zero. Both atomic orbitals and molecular orbitals can have nodal planes.

node Points in an atom at which the electron density is zero. Radial nodes are spherical surfaces, while angular nodes can be planes or cones.

nonbonding pair In a Lewis structure a pair of electrons assigned completely to one atom; also called a lone pair.

nonelectrolyte A substance that does not ionize in water and consequently dissolves to form a nonconducting solution.

nonionizing radiation Radiation that does not have sufficient energy to remove an electron from a molecule.

nonmetallic elements (nonmetals) Elements in the upper right corner of the periodic table; nonmetals differ from metals in their physical and chemical properties.

nonpolar covalent bond A covalent bond in which the electrons are shared equally.

normal boiling point The boiling point at 1 atm pressure.

normal melting point The melting point at 1 atm pressure.

nuclear binding energy The energy required to decompose an atomic nucleus into its component protons and neutrons.

nuclear disintegration series A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one; also called a radioactive series.

nuclear model Model of the atom with a very small and extremely dense nucleus containing most of the mass (protons and neutrons) and with electrons in the space outside the nucleus.

nuclear reaction Reaction in which transformations of atomic nuclei occur.

nuclear transmutation A conversion of one kind of nucleus to another.

nucleic acids Polymers of high molecular weight that carry genetic information and control protein synthesis.

nucleon Particles found in the nucleus of an atom; protons and neutrons.

nucleotide Monomers of nucleic acids formed from a five-carbon sugar, a nitrogen-containing organic base, and a phosphate group. Nucleotides form linear polymers called DNA and RNA, which are involved in protein synthesis and cell reproduction.

nucleus The very small, very dense, positively charged portion of an atom; it is composed of protons and neutrons.

octet rule A rule stating that atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons.

optical isomerism A form of isomerism in which the two forms of a compound (stereoisomers) are nonsuperimposable mirror images. Also called **enantiomers**.

optically active A substance that possesses the ability to rotate the plane of polarized light.

orbital An allowed energy state of an electron in the quantum-mechanical model of the atom; the term *orbital* is also used to describe the spatial distribution of electron density. An orbital is defined by the values of three quantum numbers: n, l, and m_l

orbital diagram A representation of an atomic orbital drawn as a box with one or two half-arrows inside representing electrons.

organic chemistry The study of carbon-containing compounds, typically containing carbon–hydrogen bonds.

osmosis The net movement of solvent through a semipermeable membrane toward the solution with greater solute concentration.

osmotic pressure The pressure that must be applied to a solution to stop osmosis from pure solvent into the solution.

Ostwald process An industrial process used to make nitric acid from ammonia. The NH_3 is catalytically oxidized by O_2 to form NO; NO in air is oxidized to NO_2; HNO_3 is formed in a disproportionation reaction when NO_2 dissolves in water.

overall reaction order The sum of the reaction orders of all the reactants appearing in the rate expression when the rate can be expressed as rate $= k[A]^a[B]^b \ldots$.

overlap The extent to which atomic orbitals on different atoms share the same region of space. When the overlap between two orbitals is large, a strong bond may be formed.

oxidation A process in which a substance loses one or more electrons.

oxidation number (oxidation state) A positive or negative whole number assigned to an element in a molecule or ion on the basis of a set of formal rules; to some degree it reflects the positive or negative character of that atom.

oxidation–reduction (redox) reaction A reaction in which electrons are transferred from one reactant to another and the oxidation states of these atoms change.

oxidizing agent, or oxidant The substance that is reduced and thereby causes the oxidation of some other substance in an oxidation–reduction reaction.

oxyacid A compound in which one or more OH groups, and possibly additional oxygen atoms, are bonded to a central atom.

oxyanion A polyatomic anion that contains one or more oxygen atoms.

ozone The name given to O_3, an allotrope of oxygen.

paramagnetism A property that a substance possesses if it contains one or more unpaired electrons. A paramagnetic substance is attracted to a magnetic field.

partial pressure The pressure exerted by a particular gas in a mixture.

particle accelerator A device that uses strong magnetic and electrostatic fields to accelerate charged particles.

parts per billion (ppb) The concentration of a solution in grams of solute per 10^9 (billion) grams of solution; equals micrograms of solute per liter of solution for aqueous solutions.

parts per million (ppm) The concentration of a solution in grams of solute per 10^6 (million) grams of solution; equals milligrams of solute per liter of solution for aqueous solutions.

pascal (Pa) The SI unit of pressure: $1\ \text{Pa} = 1\ \text{N/m}^2$.

Pauli exclusion principle A rule stating that no two electrons in an atom may have the same four quantum numbers (n, l, m_l, and m_s). As a reflection of this principle, there can be no more than two electrons in any one atomic orbital.

peptide bond An amide group formed by amino acids. A bond formed between two amino acids.

percent ionization The percent of a substance that undergoes ionization on dissolution in water. The term applies to solutions of weak acids and bases.

percent yield The ratio of the actual (experimental) yield of a product to its theoretical (calculated) yield, multiplied by 100.

period The row of elements that lie in a horizontal row in the periodic table.

periodic table The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns.

perspective drawing A model that uses wedges and dashed lines to depict bonds that are not in the plane of the paper.

petroleum A naturally occurring combustible liquid composed of hundreds of hydrocarbons and other organic compounds.

pH The negative log in base 10 of the hydrogen ion concentration: $\text{pH} = -\log[\text{H}^+]$.

pH titration curve A graph of pH as a function of added titrant.

phase change The conversion of a substance from one state of matter to another. The phase changes we consider are melting and freezing (solid $\rightleftharpoons$ liquid), sublimation and deposition (solid $\rightleftharpoons$ gas), and vaporization and condensation (liquid $\rightleftharpoons$ gas).

phase diagram A graphic representation of the equilibria among the solid, liquid, and gaseous phases of a substance as a function of temperature and pressure.

phospholipid A form of lipid molecule that contains charged phosphate groups.

photochemical smog A complex mixture of undesirable substances produced by the action of sunlight on an urban atmosphere polluted with automobile emissions. The major starting ingredients are nitrogen oxides and organic substances.

photodissociation The rupture of a chemical bond resulting from absorption of a photon by a molecule.

photoelectric effect The emission of electrons from a metal surface induced by light.

photoionization The removal of an electron from an atom or molecule by absorption of light.

photon The smallest increment (a quantum) of radiant energy; a photon of light with frequency ν has an energy equal to $h\nu$.

photosynthesis The process that occurs in plant leaves by which light energy is used to convert carbon dioxide and water to carbohydrates and oxygen.

physical changes Changes in physical appearance (such as a phase change) that occur with no change in chemical composition.

physical properties Properties that can be measured without changing the composition of a substance, for example, color and freezing point.

pi (π) bond A covalent bond in which electron density is concentrated above and below the internuclear axis; produced by the sideways overlap of *p* orbitals.

pi (π) molecular orbital A molecular orbital that concentrates the electron density on opposite sides of an imaginary line that passes through the nuclei.

Planck constant (*h*) The constant that relates the energy and frequency of a photon, $E = h\nu$. Its value is 6.626×10^{-34} J-s.

plastic A polymeric solid that can be formed into particular shapes by application of heat and pressure.

polar covalent bond A covalent bond in which the electrons are not shared equally.

polarizability The ease with which the electron cloud of an atom or a molecule is distorted by an outside influence, thereby inducing a dipole moment.

polar molecule A molecule in which the centers of positive and negative charge do not coincide; a molecule that possesses a nonzero dipole moment.

polyatomic ion An electrically charged group of two or more atoms.

polydentate ligand A ligand in which three or more donor atoms can coordinate to the same metal ion.

polymer Large molecules with long chains of atoms (usually carbon), where the atoms within a given chain are connected by covalent bonds and adjacent chains are held to one another largely by weaker intermolecular forces.

polypeptide A polymer of amino acids formed when a large number of amino acids (>30) are linked together by peptide bonds.

polyprotic acid A substance capable of dissociating more than one proton in water; H_2SO_4 is an example.

polysaccharide A substance made up of many monosaccharide units joined together.

porphyrin A complex derived from the porphine molecule.

positron A particle with the same mass as an electron but with a positive charge, ${}^{0}_{+1}\text{e}$, or β^+.

positron emission A nuclear decay process where a positron, a particle with the same mass as an electron but with a positive charge, symbol ${}^{0}_{+1}\text{e}$, or β^+, is emitted from the nucleus.

potential energy The energy that an object possesses as a result of its position with respect to another object.

precipitate An insoluble substance that forms in, and separates from, a solution.

precipitation reaction A reaction that occurs between substances in solution in which one of the products is insoluble.

precision The closeness of agreement among several measurements of the same quantity.

pressure A measure of the force exerted on a unit area. In chemistry, pressure is often expressed in units of atmospheres (atm) or torr: 760 torr $=$ 1 atm; in SI units pressure is expressed in pascals (Pa).

pressure–volume (*PV*) work Work performed by expansion of a gas against a resisting pressure.

primary cell A voltaic cell that cannot be recharged.

primary structure The sequence of amino acids along a protein chain.

primitive lattice A crystal lattice in which the lattice points are located only at the corners of each unit cell.

principal quantum number The integer, *n*, associated with orbits and energy levels in the Bohr atom.

probability density (ψ^2) A value that represents the probability that an electron will be found at a given point in space. Also called **electron density**.

product A substance produced in a chemical reaction; it appears to the right of the arrow in a chemical equation.

property Any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types.

protein Macromolecules present in all living cells; a biopolymer formed from amino acids.

protium The most common isotope of hydrogen.

proton A positively charged subatomic particle found in the nucleus of an atom.

pure substance Matter that has a fixed composition and distinct properties.

qualitative analysis The determination of the presence or absence of a particular substance in a mixture.

quantitative analysis The determination of the amount of a given substance that is present in a sample.

quantum The smallest increment of radiant energy that may be absorbed or emitted; the magnitude of radiant energy is $h\nu$.

quaternary structure The structure of a protein resulting from the clustering of several individual protein chains into a final specific shape.

racemic mixture A mixture of equal amounts of the dextrorotatory and levorotatory forms of a chiral molecule. A racemic mixture will not rotate the plane of polarized light.

rad A measure of the energy absorbed from radiation by tissue or other biological material; 1 rad = transfer of 1×10^{-2} J of energy per kilogram of material.

radial probability function The probability that the electron will be found at a certain distance from the nucleus.

radioactive Possessing radioactivity, the spontaneous disintegration of an unstable atomic nucleus with accompanying emission of radiation.

radioactive decay chain A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one. Also called **nuclear disintegration series**.

radioisotope An isotope that is radioactive; that is, it is undergoing nuclear changes with emission of radiation.

radionuclide A radioactive nuclide.

radiotracer A radioisotope that can be used to trace the path of an element in a chemical system.

Raoult's law A law stating that the partial pressure exerted by solvent vapor above the solution, P_{solution}, equals the product of the mole fraction of the solvent, X_{solvent}, and the vapor pressure of the pure solvent, $P^{\circ}_{\text{solvent}}$. $P_{\text{solution}} = X_{\text{solvent}}P^{\circ}_{\text{solvent}}$.

rare earth element See **lanthanide (rare earth) element**.

rate constant A constant of proportionality between the reaction rate and the concentrations of reactants that appear in the rate law.

rate-determining step The slowest elementary step in a reaction mechanism.

rate law An equation that relates the reaction rate to the concentrations of reactants (and sometimes of products also).

reactant A starting substance in a chemical reaction; it appears to the left of the arrow in a chemical equation.

reaction mechanism A detailed picture, or model, of how the reaction occurs; that is, the order in which bonds are broken and formed and the changes in relative positions of the atoms as the reaction proceeds.

reaction order The power to which the concentration of a reactant is raised in a rate law.

reaction quotient (Q) The value that is obtained when concentrations of reactants and products are inserted into the equilibrium expression. If the concentrations are equilibrium concentrations, $Q = K$; otherwise, $Q \neq K$.

reaction rate The speed at which a chemical reaction occurs; a measure of the decrease in concentration of a reactant or the increase in concentration of a product with time.

redox (oxidation–reduction) reaction A reaction in which certain atoms undergo changes in oxidation states. The substance increasing in oxidation state is oxidized; the substance decreasing in oxidation state is reduced.

reducing agent, or reductant The substance that is oxidized and thereby causes the reduction of some other substance in an oxidation–reduction reaction.

reduction A process in which a substance gains one or more electrons.

rem A measure of the biological damage caused by radiation; rems = rads × RBE.

renewable energy sources Energy such as solar energy, wind energy, and hydroelectric energy derived from essentially inexhaustible sources.

representative (main-group) element An element from within the s and p blocks of the periodic table.

resonance structures (resonance forms) Individual Lewis structures in cases where two or more Lewis structures are equally good descriptions of a single molecule. The resonance structures in such an instance are "averaged" to give a more accurate description of the real molecule.

reverse osmosis The process by which water molecules move under high pressure through a semipermeable membrane from the more concentrated to the less concentrated solution.

reversible process A process in which the system can be restored to its original condition with no change to the surroundings.

ribonucleic acid (RNA) A polynucleotide in which ribose is the sugar component.

root-mean-square (rms) speed (μ_{rms}) The square root of the average of the squared speeds of the gas molecules in a gas sample.

rotational motion Movement of a molecule as it spins about an axis.

salinity A measure of the salt content of seawater, brine, or brackish water. It is equal to the mass in grams of dissolved salts present in 1 kg of seawater.

salt Any ionic compound whose cation comes from a base (for example, Na^+ from NaOH) and whose anion comes from an acid (for example, Cl^- from HCl).

saponification Hydrolysis of an ester in the presence of a base.

saturated solution A solution in which undissolved solute and dissolved solute are in equilibrium.

scientific law A statement of what is always observed to happen, to the best of our knowledge.

scientific method The general process of advancing scientific knowledge by making experimental observations and by formulating hypotheses, theories, and laws.

secondary cell A voltaic cell that can be recharged.

secondary structure Refers to how segments of the protein chain are oriented in a regular pattern.

second law of thermodynamics A statement that relates the change in the entropy of the universe (ΔS_{univ}) to the reversibility of the process. For a reversible process, $\Delta S_{\text{univ}} = 0$. For an irreversible process, $\Delta S_{\text{univ}} > 0$. Because spontaneous processes are irreversible, the second law means that in any spontaneous process the entropy of the universe increases.

second-order reaction A reaction in which the rate depends either on a reactant concentration raised to the second power or on the concentrations of two reactants each raised to the first power.

semiconductor A material that has electrical conductivity between that of a metal and that of an insulator.

sigma (σ) bond A covalent bond in which electron density is concentrated along the internuclear axis.

sigma (σ) molecular orbital A molecular orbital that centers the electron density about an imaginary line passing through two nuclei.

significant figures The digits that indicate the precision with which a measurement is made; all digits of a measured quantity are significant, including the last digit, which is uncertain.

silica Common name for silicon dioxide.

silicates Compounds containing silicon and oxygen, structurally based on SiO_4 tetrahedra.

single bond A covalent bond involving one electron pair.

SI units The preferred metric units for use in science.

smectic A and smectic C liquid crystals Liquid crystals in which the molecules maintain the long-axis alignment seen in nematic crystals, but in addition pack into layers.

solid Matter that has both a definite shape and a definite volume.

solubility The amount of a substance that dissolves in a given quantity of solvent at a given temperature to form a saturated solution.

solubility-product constant (solubility product, K_{sp}) An equilibrium constant related to the equilibrium between a solid salt and its ions in solution. It provides a quantitative measure of the solubility of a slightly soluble salt.

solute A substance dissolved in a solvent to form a solution; it is normally the component of a solution present in the smaller amount.

solution A mixture of substances that has a uniform composition; a homogeneous mixture.

solvation The clustering of solvent molecules around a solute particle.

solvent The dissolving medium of a solution; it is normally the component of a solution present in the greater amount.

space-filling model Model that shows relative sizes of the atoms.

specific heat (C_s) The heat capacity of 1 g of a substance; the heat required to raise the temperature of 1 g of a substance by 1 °C.

spectator ions Ions that go through a reaction unchanged and that appear on both sides of the complete ionic equation.

spectrochemical series A list of ligands arranged in order of their abilities to increase the crystal-field splitting energy.

spectrum The distribution among various wavelengths of the radiant energy emitted or absorbed by an object.

spin magnetic quantum number (m_s) A quantum number associated with the electron spin; it may have values of $+\frac{1}{2}$ or $-\frac{1}{2}$.

spin-pairing energy The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital.

spontaneous process A process that is capable of proceeding in a given direction, as written or described, without needing to be driven by an outside source of energy. A process may be spontaneous even though it is very slow.

standard atmospheric pressure Defined as 760 torr or, in SI units, 101.325 kPa.

standard emf, also called the standard cell potential ($E°$) The emf of a cell when all reagents are at standard conditions.

standard enthalpy change ($\Delta H°$) The change in enthalpy in a process when all reactants and products are in their stable forms at 1 atm pressure and a specified temperature, commonly 25 °C.

standard enthalpy of formation ($\Delta H_f°$) The change in enthalpy that accompanies the formation of one mole of a substance from its elements, with all substances in their standard states.

standard free energy of formation ($\Delta G_f°$) The change in free energy associated with the formation of a substance from its elements under standard conditions.

standard hydrogen electrode (SHE) An electrode based on the half-reaction $2\,H^+(1\,M) + 2\,e^- \longrightarrow H_2(1\text{ atm})$. The standard electrode potential of the standard hydrogen electrode is defined as 0 V.

standard molar entropy ($S°$) The entropy value for a mole of a substance in its standard state.

standard reduction potential ($E°_{\text{red}}$) The potential of a reduction half-reaction under standard conditions, measured relative to the standard hydrogen electrode. A standard reduction potential is also called a standard electrode potential.

standard solution A solution of known concentration.

standard temperature and pressure (STP) Defined as 0 °C and 1 atm pressure; frequently used as reference conditions for a gas.

starch The general name given to a group of polysaccharides that acts as energy-storage substances in plants.

state function A property of a system that is determined by its state or condition and not by how it got to that state; its value is fixed when temperature, pressure, composition, and physical form are specified; P, V, T, E, and H are state functions.

states of matter The three forms that matter can assume: solid, liquid, and gas.

stereoisomers Compounds possessing the same formula and bonding arrangement but differing in the spatial arrangements of the atoms.

stoichiometry The relationships among the quantities of reactants and products involved in chemical reactions.

stratosphere The region of Earth's atmosphere from 10 km to 50 km above the surface.

strong acid An acid that ionizes completely in water.

strong base A base that ionizes completely in water.

strong electrolyte A substance (strong acids, strong bases, and most salts) that is completely ionized in solution.

structural formula A formula that shows not only the number and kinds of atoms in the molecule but also the arrangement (connections) of the atoms.

structural isomers Compounds possessing the same formula but differing in the bonding arrangements of the atoms.

subatomic particles Particles such as protons, neutrons, and electrons that are smaller than an atom.

subshell One or more orbitals with the same set of quantum numbers n and l. For example, we speak of the $2p$ subshell ($n = 2, l = 1$), which is composed of three orbitals ($2p_x$, $2p_y$, and $2p_z$).

substitutional alloy An alloy formed when atoms of the solute in a solid solution occupy positions normally occupied by a solvent atom.

substitution reactions Reactions in which one atom (or group of atoms) replaces another atom (or group) within a molecule; substitution reactions are typical for alkanes and aromatic hydrocarbons.

substrate A substance that undergoes a reaction at the active site in an enzyme.

supercritical fluid The state that exists when liquid and gas phases are indistinguishable from each other as the temperature exceeds the critical temperature and the pressure exceeds the critical pressure.

supercritical mass An amount of fissionable material larger than the critical mass.

supersaturated solution A solution containing more solute than an equivalent saturated solution.

surface tension The energy required to increase the surface area of a liquid by a unit amount.

surroundings In thermodynamics, everything that lies outside the system that we study.

system In thermodynamics, the portion of the universe that we single out for study. We must be careful to state exactly what the system contains and what transfers of energy it may have with its surroundings.

temperature A measure of the hotness or coldness of an object; a physical property that determines the direction of heat flow.

termolecular reaction An elementary reaction that involves three molecules. Termolecular reactions are rare.

tertiary structure The overall shape of a large protein, specifically, the manner in which sections of the protein fold back upon themselves or intertwine.

theoretical yield The quantity of product that is calculated to form when all of the limiting reagent reacts.

theory A tested model or explanation that has predictive powers and that accounts for all available observations.

thermochemistry The relationship between chemical reactions and energy changes.

thermodynamics The study of energy and its transformation.

thermonuclear reaction Another name for fusion reactions; reactions in which two light nuclei are joined to form a more massive one.

thermoplastic A polymeric material that can be readily reshaped by application of heat and pressure.

thermosetting plastic A plastic that is formed by irreversible chemical processes and therefore is not readily reshaped by application of heat and pressure.

third law of thermodynamics A law stating that the entropy of a pure, crystalline solid at absolute zero temperature is zero: $S(0\text{ K}) = 0$.

titration The process of reacting a solution of unknown concentration with one of known concentration (a standard solution).

torr A unit of pressure (1 torr = 1 mm Hg).

transition elements (transition metals) Elements in which the d orbitals are partially occupied.

transition state (activated complex) The particular arrangement of reactant and product molecules at the point of maximum energy in the rate-determining step of a reaction.

translational motion Movement in which an entire molecule moves in a definite direction.

transuranium elements Elements that follow uranium in the periodic table.

triple bond A covalent bond involving three electron pairs.

triple point The temperature at which solid, liquid, and gas phases coexist in equilibrium.

tritium The isotope of hydrogen whose nucleus contains a proton and two neutrons.

troposphere The region of Earth's atmosphere extending from the surface to about 10 km altitude.

Tyndall effect The scattering of a beam of visible light by the particles in a colloidal dispersion.

uncertainty principle A principle stating there is an inherent uncertainty in the precision with which we can simultaneously specify the position and momentum of a particle. This uncertainty is significant only for particles of extremely small mass, such as electrons.

unimolecular reaction An elementary reaction that involves a single molecule.

unit cell The smallest portion of a crystal that reproduces the structure of the entire crystal when repeated in different directions in space. It is the repeating unit or building block of the crystal lattice.

unsaturated solution A solution containing less solute than a saturated solution.

valence band A band of closely spaced bonding molecular orbitals that is essentially fully occupied by electrons.

valence-bond theory A model of chemical bonding in which an electron-pair bond is formed between two atoms by the overlap of orbitals on the two atoms.

valence electrons The outermost electrons of an atom; those that occupy orbitals not occupied in the nearest noble-gas element of lower atomic number. The valence electrons are the ones the atom uses in bonding.

valence orbitals Orbitals that contain the outer-shell electrons of an atom.

valence-shell electron-pair repulsion (VSEPR) model A model that accounts for the geometric arrangements of shared and unshared electron pairs around a central atom in terms of the repulsions between electron pairs.

van der Waals equation An equation of state for nonideal gases that is based on adding corrections to the ideal-gas equation. The correction terms account for intermolecular forces of attraction and for the volumes occupied by the gas molecules themselves.

van't Hoff factor The number of fragments that a solute breaks into for a particular solvent.

vapor Gaseous state of any substance that normally exists as a liquid or solid.

vapor pressure The pressure exerted by a vapor in equilibrium with its liquid or solid phase.

vibrational motion Movement of the atoms within a molecule in which they move periodically toward and away from one another.

viscosity A measure of the resistance of fluids to flow.

volatile Refers to liquids that evaporate readily.

voltaic (galvanic) cell A device in which a spontaneous oxidation–reduction reaction occurs with the passage of electrons through an external circuit.

vulcanization The process of cross-linking polymer chains in rubber.

watt A unit of power; $1\ \text{W} = 1\ \text{J/s}$.

wave function A mathematical description of an allowed energy state (an orbital) for an electron in the quantum-mechanical model of the atom; it is usually symbolized by the Greek letter ψ.

wavelength The distance between identical points (such as two adjacent peaks or two adjacent troughs) on successive waves.

weak acid An acid that only partly ionizes in water.

weak base A base that only partly ionizes in water.

weak electrolyte A substance that only partly ionizes in solution.

work The energy transferred when a force exerted on an object causes a displacement of that object.

zeolite A class of aluminosilicates that occur naturally and can also be synthesized.

zero-order reaction A reaction in which the rate of disappearance of A is independent of [A].

INDEX

Note: Page references with *f* indicate a figure on that page; *t* indicates table; *n* indicates note.

A

Absolute zero, 18, 397
Absorption, 551, 601
Absorption spectrum, 1000, 1000*f*
Accuracy, 23, 23*f*, 24*f*
Acetaldehyde, 1035*t*
Acetamide, 4, 1035*t*
Acetic acid (CH_3COOH), 128*f*, 129, 1035*t*
    chemical formula for, 122*n*
    hydrogens in, 129
    molecular model of, 128*f*
    strength of, 122
Acetic ion (CH_3COOH^- or $C_2H_3O_2^-$), 67*t*, 122, 125*t*
Acetone, 529, 1035*t*
Acetylsalicylic acid (aspirin), 131*n*
Acid-base equilibria, 661–712
    acid-base behavior and chemical structure, 697–701, 698–699*f*
    acid-base properties of salt solutions, 693–697, 694*t*, 695*f*
    Arrhenius acids and bases, 662
    autoionization of water, 669–670*f*, 669–671
    Brønsted-Lowry acids and bases, 663–664, 663–664*f*
    classifications of acids and bases, 662–666, 663–664*f*
    conjugate acid-base pairs, 666–669, 668*f*
    Lewis acids and bases, 665–666
    pH scale, 671–675, 672*t*, 673–675
    relationship between *Ka* and *Kb*, 691–693, 692*ft*
    strong acids, 675–676
    strong bases, 676–677
    weak acids, 677–687, 678*ft*, 682–684*f*, 685*t*
    weak bases, 687–690, 688*f*
Acid-base indicator, 148, 149*f*, 732–733, 733–734*f*
Acid-base properties
    of chromium oxides, 947–948, 948*t*
    of organic molecules, 1023, 1023*f*
Acid-base titrations, 726–736, 727*f*, 728–729*f*, 732–735*f*
    with an acid-base indicator, 732–733, 733–734*f*
    equivalence point, 727, 728, 729*f*, 730
    pH titration curve, 725–726, 726*f*
    of polyprotic acids, 734–735, 735*f*
    strong, 726*f*, 726–728
    in the laboratory, 735–736
    weak, 728–729*f*, 728–732, 732*f*
Acid-dissociation constant, 677–678, 678*f*
Acidic anhydrides, 947
Acidic aqueous solutions, 670, 842–845
Acid inhibitors, 134, 134*ft*
Acid-insoluble sulfides, 751, 752*f*
Acid-neutralizing agents, 134, 134*ft*
Acidosis, 724
Acid rain, 135, 772*ft*, 772–773, 773*f*, 790
Acids, 128*f*, 128–129. *See also* Acid-base equilibria
    amphiprotic behavior of amino acids, 701
    binary acids, 698, 699*f*
    carboxylic acids, 700, 701
    classifications of, 662–666, 663–664*f*
    conjugate, 666–667
    conjugate base stability, 698
    diluting concentrated, 145*n*
    diprotic, 128
    H—A bond polarity, 697
    H—A bond strength, 698
    household, 128, 128*f*
    molecular models of, 128, 128*f*
    monoprotic, 128
    oxidation of metals by, 138*f*, 138–139
    oxyacids, 698–699, 699*f*
    predicting relative acidities from composition and structure, 700
    in rain, 135
    stomach, antacids and, 134, 134*ft*
    strength of
        factors that affect, 697–698, 698*f*
        relative, 667–668, 668*f*
    strong, 675–676
    strong and weak, 129*t*, 129–130
    titration, 148–150, 149*f*
    weak, 677–687, 678*ft*, 682–684*f*, 685*t*
Acid salts, 692
Actinide elements, 240, 243*f*
Activated complex, 586
Activation-controlled reactions, 598
Activation energy, 585–587*f*, 585–589
Active electrodes, 876
Active metals, 139, 140*t*
Active site, 602–603
Activity, in radioactive decay, 904–905
Activity series, 139–140, 140*t*, 141*f*
Actual yield, 108
Addition, significant figures in, 25
Addition polymerization/polymers, 498, 499*t*
Addition reactions, 1030–1031
Adenine, 1054, 1055, 1055*f*, 1057
Adhesive forces, 443, 443*f*
Adipic acid, 498, 499*f*
Adsorption, 551, 601
Advanced burning, 919, 919*f*
Alanine, 1044*f*
Albuterol, 1042, 1042*f*
Alcohol group, 1034
Alcohols, 73–74, 131, 529, 529*t*, 1034, 1034*f*, 1035*t*, 1036
Aldehydes, 1035*t*, 1036–1037
Alkali metal halides, 486*t*
Alkali metal ions and NH_4^+, 752, 752*f*
Alkali metals (group 1A elements)
    covalent bonding, 304–306, 305*f*
    energetics of ionic bond formation, 300*t*, 300–303, 302*f*, 303*f*
    ionic charges, 60, 60*f*
    ions, 124, 137
    in periodic table, 54*f*, 55*t*, 60, 239, 240–241
    properties of, 276–278, 277*ft*, 277*t*, 278*f*, 279*f*
    reactivity of, 277*f*, 277–278, 278*f*, 279*f*
    trends for, 276–280, 277*ft*, 278*f*, 279*f*
Alkaline batteries, 869, 869*f*
Alkaline earth metals (group 2A elements)
    covalent bonding, 304–306, 305*f*
    energetics of ionic bond formation, 300*t*, 300–303, 302*f*, 303*f*
    ionic charges, 60, 60*f*
    in periodic table, 54*f*, 55*t*, 241, 241*t*, 243*f*
    properties of, 280*t*, 280–281, 281*f*
    reactivity of, 280–281, 281*f*
    trends for, 280*t*, 280–281, 281*f*
Alkaline earth metals, in periodic table, 55*t*, 56, 60
Alkalosis, 724
Alkanes, 1024*t*, 1024–1026, 1025–1026*f*
    common names for, 72*t*
    cycloalkanes, 1026, 1026*f*
    defined, with molecular examples, 1024, 1024*t*

Alkanes (*Continued*)
  isomers, 1025, 1026*f*
  methods for naming, 72*t*, 72–73
  nomenclature of, 71–73, 72*t*
  reactions of, 1026
  straight-chain, 70, 70*t*
  structures of, 1025, 1025*f*
Alkenes, 1027–1028*f*, 1027–1029
  addition reactions of, 1030–1031
  defined, with molecular examples, 1024, 1024*t*
  isomers, 1027–1028, 1027–1028*f*
Alkyl groups, 72, 72*t*, 1028, 1033, 1034, 1040
Alkynes, 1029–1030
  addition reactions of, 1030–1031
  defined, with molecular examples, 1024, 1024*t*
Allotropes, 282, 935
Alloys, 480*t*, 480–481, 480–481*f*
  melting point of, 480*t*, 481
Alloy steels, 481
Alpha (α) decay, 893
Alpha (α) emissions, 893, 895*t*
Alpha (α) particles, 892–893
Alpha (α) radiation, 892–893, 893*t*, 894*t*, 895*t*
A-amino acids, 1043
A-carbon atom, 1044, 1045
A-helix, 1046
Aluminum (Al)
  electrometallurgy of, 878, 878*f*
  electron configuration, 241*t*, 243*f*
  ionization energy, 268*t*
  oxidation reaction, 140*t*
Aluminum ion (Al^{3+}), 64*t*
Alzheimer's disease, 908, 909*f*
Amides, 1035*t*, 1041
Amine(s), 688, 688*f*, 692, 692*f*
Amine hydrochlorides, 692, 692*f*
Amines, 1035*t*, 1040
Amino acids, 1043–1045, 1044*f*
Amino acids, amphiprotic behavior of, 701
Ammonia (NH_3), 129, 130, 624, 624*f*, 641, 642*f*, 664, 664*f*, 953, 953*f*, 988*t*
Ammonium ions (NH_4^+), 64*t*, 122, 124, 125*t*, 571, 571*t*, 572
Ammonium perchlorate (NH_4ClO_4), 945
Ampere (A or amp), 17*t*
Amphiprotic base, 664
Amphiprotic behavior of amino acids, 701
Amphoteric hydroxides, 746*f*, 746–747
Amphoteric oxides, 746*f*, 746–747, 947
Amphoterism, 746*f*, 746–747
Anaerobic reaction, 196
Anemia, 989
Angina, nitroglycerin for relieving, 197–198
Angstrom (Å), 48, 213*t*
Angular momentum quantum number *(l)*, 226–227, 228, 228*ft*
Angular node, 232
Anionic ligands, 993
Anions
  coordination numbers, 487, 488–489*f*
  defined, 59
  electron affinity, 270*n*, 270–272, 271*f*
  halogens, 283–285, 284*ft*
  ionic structure, 487, 488–489*f*
  ionization energy, 267*f*, 267–270, 268*t*, 269*f*
  monatomic, 65
  names and formulas for, 65*f*, 65–66, 66*f*, 67*t*
  oxyanions, 65*f*, 65–66, 66*f*
  relating relative numbers of to chemical formulas, 123
Anodes
  batteries and fuel cells, 867–868*f*, 867–873, 870–872*f*
  in cathode-ray tube, 43–44, 44*f*
  cell potentials under nonstandard conditions, 861–867, 864*f*, 865*f*
  cell potentials under standard conditions, 850*f*, 850–857, 851–852*f*, 853*t*, 856*f*
  corrosion, 873–875, 874–875*f*
  defined, 43, 839, 848
  electrolysis, 876–877*f*, 876–879
  free energy and redox reactions, 857–861, 859*f*
  in lithium-ion batteries, 266, 266*f*
  oxidation states and oxidation-reduction reactions, 840*f*, 840–841
  redox equations, balancing, 842*f*, 842–847, 843*f*
  voltaic cells, 847–849*f*, 847–850
Anomalous electron configurations, 243*f*, 243–244
Antacids, 134, 134*ft*
Antibonding molecular orbital, 365*f*, 366, 370*f*, 372
Antiferromagnetism, 981*f*, 981–982
Antimony (Sb), 956*t*, 959
Aqueous equilibria, 713–762
  acid-base titrations, 726–736, 727*f*, 728–729*f*, 732–735*f*
  buffers, 717*f*, 717–725, 718*f*, 722*f*
  common-ion effect, 714–716
  ions, precipitation and separation of, 748–751, 750*f*
  precipitation and separation of ions, 748–751, 750*f*
  qualitative analysis for metallic elements, 751–752, 752*f*
  solubility, factors that affect, 741*f*, 741–748, 743*f*, 744*f*, 745*t*, 746*f*
  solubility equilibria, 737–740, 739*f*
Aqueous solutions, 119–160
  acids, 128*f*, 128–129, 129*t*, 842–845
  balancing redox equations in, 842–845
  bases, 129, 129*ft*
  concentrations of solutions, 142–147, 143*f*, 146*f*
  defined, 119
  electrolytes and nonelectrolytes, 120, 120*f*
  how compounds dissolve in water, 121*f*, 121–122
  precipitation reactions, 123–127
  strong and weak acids and bases, 129*t*, 129–130
  strong and weak electrolytes, 122, 130, 130*t*
  symbols for, 89
Arginine, 1044*f*
Argon (Ar)
  in Earth's atmosphere, 765*t*
  electron configuration, 285*t*
  ionization energy, 268*t*
  Lewis symbol for, 298, 298*f*
  in periodic table, 53, 53*f*
  properties of, 285, 285*t*
  uses of, 941
Aristotle, 42
Arnold, Frances, 605, 605*f*
Aromatic hydrocarbons, 1031–1032, 1032*f*
  defined, with molecular examples, 1024, 1024*t*
  line formulas and common names of, 1031–1032, 1032*f*
  phenyl group, 1031
  substitution reactions of, 1032–1033
Aromatic organic compound, benzene as, 318–319, 319*f*
Array detector, 474, 474*f*
Arrhenius, Svante, 587, 662
Arrhenius acids and bases, 662
Arrhenius equation, 587
Arsenic (As)
  chemistry of, 956*t*, 959
  in drinking water, 959–960, 960*f*
Asbestos, 965–966
A-scattering experiment, 46–47, 47*f*
Ascorbic acid (vitamin C), 131*n*
Asparagine, 1044*f*
Aspartame, 1045, 1045*f*

Aspartic acid, 1044*f*
Aspirin (acetylsalicylic acid), 131*n*
Astatine-210, 942
Atmosphere, 394, 582, 582*f*
Atmospheric pressure
  barometer and, 393–394, 394*f*
  enthalpy, 170*n,* 171, 173, 184–185
  standard, 394
  units of measure for, 393*f,* 393–395, 394*f*
Atom(s)
  atomic mass scale, 51
  atomic mass unit (amu) of, 48, 48*t,* 51
  atomic number in, 49–50
  atomic size, 49
  atomic structure, 43–51
  atomic theory of matter, 42*f,* 42–43
  atomic weight of, 51–53
  bonding atomic radius, 261*f,* 261–264, 262*f,* 263, 264*f*
  corner, 475–476, 476*f*
  crystal lattices, 471–472*f,* 471–473
  defined, 2, 41
  electronic charge of, 48
  electronic structure of (*See* Electronic structure of atoms)
  in elemental form, oxidation number of, 136
  formal charge in Lewis structures, 314–315, 316
  isotopes, 50, 50*t*
  Lewis structures, 304–306, 312–317, 316*f*
  mass number in, 49–50, 50*t*
  metallic solids, 470, 470*f,* 475–476*f,* 475–482, 477*t,* 478–479*f,* 480*t,* 480–481*f*
  motif, 473, 473*f*
  noble-gas core of, 239
  nuclear model of, 46*f,* 46–47, 257
  oxidation numbers assigned to, 316
  periodic trends in atomic radii, 263
  size of, 49
  sizes of, 261*f,* 261–267, 262*f,* 264*f*
  subatomic particles in, 43, 48, 49, 50
  symbols for, 50, 58
Atomic bomb, 914*f,* 914–915, 915*f,* 918*n*
Atomic chlorine, mass spectrum of, 52*f*
Atomic mass scale, 51
Atomic mass unit (amu), 48, 48*t,* 51
Atomic nitrogen (N), 96–97, 97*t,* 768
Atomic numbers, 49–50, 257, 892
  alkali metals, 277
  concept of, 257
  in development of periodic table, 256
  effective nuclear charge, 260, 260*f*
  halogens, 284

- Krypton (Kr)
  - compounds of, 941
  - in Earth's atmosphere, 765*t*
  - electron configuration, 285*t*
  - properties of, 285, 285*t*
  - uses of, 941

L

- Lactose, 1049–1050, 1050*f*
- Lanthanide contraction, 979
- Lanthanide elements, 240, 243*f*
- Lattice energy, 300*t*, 300–303, 302*f*, 303*f*
  - defined, 300
  - magnitudes of, 301
  - periodic table, 300*t*, 300–303, 302*f*, 303*f*
  - of some ionic compounds, 300*t*, 300–301
- Lattice points, 471, 471*f*
- Lattice vectors, 471, 471*f*
- Lauterbur, Paul, 236
- Law of combining volumes, 397
- Law of conservation of mass, 22, 42, 86, 103*f*
- Law of constant composition, 8, 42
- Law of definite proportions, 8
- Law of mass action, 625
- Law of multiple proportions, 42
- Lead (Pb)
  - in alloys, 480*t*
  - chemistry of, 964*t*, 964–966*f*, 964–967
  - general characteristics of, 964, 964*t*
  - nuclear synthesis, 919
  - oxidation reaction, 140*t*
- Lead-acid batteries, 868, 868*f*, 871
- Lead contamination in drinking water, 747, 747*f*
- Lead iodide (PbI_2), 123, 124*f*, 126, 127
- Lead nitrate, $Pb(NO_3)_2$, 123, 124*f*, 126, 127
- Lead(II) or plumbous ion (Pb^{2+}), 64*t*, 125*t*, 127
- Le Châtelier, Henri-Louis, 641–642
- Le Châtelier's principle, 641–649
  - catalysts, effect of, 648*f*, 648–649, 649*t*
  - change in reactant or product concentration, 643–644
  - diagram of industrial production of ammonia using Haber process, 641, 642*f*
  - effect of adding H_2 to an equilibrium mixture of N_2, H_2, and NH_3, 643, 643*f*
  - effect of temperature and pressure on NH_3 yield in Haber process, 641, 642*f*
  - effects of temperature change, 645–647, 646*f*, 647*f*
  - effects of volume and pressure changes, 644–645, 645*f*
  - endothermic and exothermic reactions, 646–647, 647*f*
  - to predict shifts in equilibrium, 647–648
  - summary of, 642*f*
- Length, 18
- Lengths for single, double, and triple bond enthalpies, 323–324, 324*ft*
- Leptons, 48
- Leucine, 1044*f*
- Leveling effect, 668
- Levorotatory isomer, 997
- Lewis, G. N., 298, 304, 665
- Lewis acids and bases, 665–666
- Lewis electron-dot symbols. *See* Lewis symbols
- Lewis structure, 304–306, 312–317, 316*f*
  - actual partial charges of atoms in, 316, 316*f*
  - of a compound, 306
  - defined, 304–305
  - dominant, identifying, 315
  - drawing, 312–317
  - formal charge of atoms in, 314–315, 316
  - of phosphorous acid (H_3PO_3), 702
  - resonance structures, 317*f*, 317–319, 318*f*, 319*f*
- Lewis symbols, 298, 298*f*
- Ligands, 987–992, 988*t*, 988–991*f*
  - bidentate, 987, 988*ft*, 988–989, 991
  - chelate effect, 989, 991
  - chelating agents, 987–989
  - chlorophylls, 991, 991*f*
  - common, 994*t*
  - crystal-field theory, 1001–1005*f*, 1001–1009, 1007*f*
  - defined, 982
  - donor atom of, 987
  - ligand-to-metal charge-transfer transitions, 1008–1009, 1008–1009*f*
  - metal-ligand bonds, 985*f*, 985–986, 1001, 1001*f*
  - metal-to-ligand charge-transfer transition, 1009
  - monodentate, 987, 988, 988*t*, 991
  - naming, 993
  - photosynthesis, 991, 991*f*
  - polydentate, 987, 988*t*, 988–989, 989*f*, 991
  - strong-field, 1003
  - weak-field, 1003
- Ligand-to-metal charge-transfer (LMCT) transition, 1008–1009, 1008–1009*f*
- Light, from alkali metals, 278, 278*f*, 279*f*
- Light-emitting diodes (LEDs), 495, 495*f*
- Light water reactors, 916
- Lime, 91
- Limiting reactants, 106–108
  - calculating amount of product formed from, 107
  - defined, 106, 107*f*
  - theoretical and percent yields, 108
- Linear accelerator, 900–901, 901*f*
- Linear hydrocarbons, 1025
- Linear molecules, 336, 337, 337*f*, 339, 339*f*, 340*t*, 341*t*, 342, 344*t*, 348, 349*t*, 352–353, 353*f*, 356*t*, 359
- Line formulas, for aromatic hydrocarbons, 1031–1032, 1032*f*
- Line spectra, 217*f*, 217–218, 218*f*
- Line structures
  - of carbohydrates, 1048, 1048*f*
  - of cycloalkanes, 1026, 1026*f*
- Lipids, 1052–1053, 1052–1053*f*
  - defined, 1052
  - phospholipids, 1053, 1053*f*
  - structure of, 1052, 1052*f*

Liquid(s), 431–468
  intermolecular forces, 433–442, 434t, 434–441f
  ionic, 444, 444f
  liquid crystals, 455–456f, 455–457
  molecular comparison of gases, solids, and, 432t, 432–433, 433f
  motion in, 553
  nonpolar, 529
  phase changes, 445–447f, 445–449, 448t
  phase diagrams, 452–454, 452–454f
  polar, 529
  properties of, 4, 5, 5f, 442f, 442–445, 443f, 444t
    capillary action, 443f, 443–444
    viscosity, 442t, 442–443, 442–443f
  supercritical fluid, 449, 453
  symbols for, 89
  vapor pressure, 449–451f, 449–452
Liquid crystals, 455–456f, 455–457
  cholesteric liquid crystal phase, 455f, 455–456
  liquid phase, 455–456, 455–456f
  nematic liquid crystal phase, 455f, 455–456
  properties of, 457
  smectic A and smectic C liquid crystal phase, 455f, 455–456
  types of, 455–456, 455–456f
Liquid phase, 455–456, 455–456f
Liter (L), 17f, 19, 19f
Lithium (Li)
  drugs, improbable development of, 279–280, 280f
  electron configuration, 237t, 237–238, 239, 243f, 277t
  lithium-ion batteries, ionic size and, 266, 266f
  oxidation reaction, 140t
  in periodic table, 53, 53f
  properties of, 277t, 278
Lithium chloride (LiCl), 300t, 302f
Lithium cobalt oxide ($LiCoO_2$), 870, 870f, 871
Lithium fluoride (LiF), 300t, 307, 308, 308f, 311, 486t
Lithium iodide (LiI), 300t
Lithium-ion batteries, ionic size and, 266, 266f
Lithium-ion (Li-ion) batteries, 869–870, 870f, 871
Litmus paper, 131, 131f
Localized molecular bonds, 361–363, 362f, 363f
Lock-and-key model for enzyme action, 603, 603f
London dispersion forces, 435
Lone pairs, 305, 339, 345, 354, 356f
Low-density polyethylene (LDPE), 497t, 501
Lowest unoccupied molecular orbitals (LUMO), 378, 378f
Lowry, Thomas, 663
Low-spin complex, 1005f, 1005–1006
Lysine, 1044f
Lysozyme, 603, 603f

M

Macroporous materials, 505, 505f
Magic numbers, 897–898
Magnesite ($MgCO_3$), 963–964
Magnesium (Mg)
  electron configuration, 241t, 243f, 280t
  ionization energy, 268t
  oxidation number, 138, 138f
  oxidation reaction, 140t
  properties of, 280t
Magnesium hydroxide ($Mg(OH)_2$), 125, 132, 134t
Magnesium ions (Mg^{2+}), 64t, 125, 780t
Magnetic quantum number (m_l), 227, 228, 228t
Magnetic resonance imaging (MRI), 236, 236f

    - alkali metals (group 1A elements), trends for, 276–280, 277*ft*, 278*f*, 279*f*
    - alkaline earth metals (group 2A elements), trends for, 280*t*, 280–281, 281*f*
    - characteristic properties of, 273*t*
  - noble gases, 285, 285*t*
  - nonmetals, 275*f*, 275–276
    - chalcogens (group 6A elements), trends for, 282*t*, 282–283, 283*f*
    - characteristic properties of, 273*t*
    - halogens (group 7A elements), trends for, 283–285, 284*ft*
    - hydrogen (H), trends for, 281–282
    - noble gases (group 8A elements), trends for, 285, 285*t*
    - trends for selected, 281–286
  - octet rule, 298, 298*f*
  - oxygen group, 282*t*, 282–283
  - periods in, 54, 54*f*
  - regions of, 240–241, 241*t*
  - for remembering ionic charges, 60, 60*f*
  - sizes of atoms and ions, 261*f*, 261–267, 262*f*, 264*f*
  - stable isotopes for elements, 898, 899*f*
- Periodic trends, 934*f*, 934–935, 935*f*
- Periods, in periodic table, 54, 54*f*
- Peroxides, 137, 948, 948*f*
- Perspective drawings, 58, 58*f*
- Perspiration, 181, 181*f*
- Petroleum, 194, 195*f*
- Pewter, 480*t*
- Pfizer-BioNTech vaccine, 1056
- pH, 671–675, 672*t*, 673–675
  - buffers and, 718–724, 722*f*, 724*f*
  - calculating, from H^+, 672, 672*t*
  - calculating H^+ from pOH, 674
  - calculating K_a from, 679
  - concentration cells for determining, 866–867
  - defined, 671, 671*n*
  - to determine the concentration of a salt, 690
  - K_a to calculate, 680–682
  - *Kb* to calculate OH^- and, 689
  - measuring pH, 673–675, 673–675*f*
  - pOH and other pH scales, 673, 673*f*
  - polyprotic acids and, 685–686
  - quadratic equation to calculate, 683–684
  - ranges for common acid–base indicators, 674*f*, 674–675
  - relationships among H^+, OH^-, and, 672, 672*t*
  - solubility and, 742–743, 743*f*
  - solutions containing three common acid–base indicators at various pH values, 675, 675*f*
  - of a strong base, calculating, 677
  - titration curve, 725–726, 726*f*
- Phase changes, 445–447*f*, 445–449, 448*t*
  - critical temperature and pressure, 448*t*, 448–449
  - energy changes with phase changes, 445–446, 445–446*f*
  - at equilibrium, relating ΔG to, 824–825
  - heating curves, 446–447, 447*f*
- Phase diagrams, 452–454, 452–454*f*, 453*f*
  - critical point, 453
  - curves, 453, 453*f*
  - defined, 452
  - generic, for pure substance, 452*f*
  - of H_2O and CO_2, 453, 453*f*
  - interpreting, 454, 454*f*
  - normal melting point, 453
  - triple point, 453, 453*f*
- Phenol, 1036
- Phenylalanine, 1044*f*
- Phenyl group, 1031
- PH meter, 673*f*, 673–674

Phosgene, 325
Phosphate ion (PO_4^{3-}), 67t, 125t, 989
Phospholipids, 1053, 1053f
Phosphorous acid (H_3PO_3), 701, 702
Phosphors, 906–907
Phosphorus (P)
  chemistry of, 956t, 956–959, 957–958f
  essential for life, 62, 62f
  ionization energy, 268t
  occurrence, isolation, and properties of, 956–957, 957f
  oxy compounds of, 957–959, 958f
  as a radiotracer, 908t
Phosphorus halides, 957
Phosphorus trichloride (PCl_3), 313, 957
Photochemical reactions in Earth's atmosphere, 766–767, 767f
Photochemical smog, 774, 774f
Photodissociation, 766–767
Photoelectric effect, 214, 215f, 215–216
Photoionization reactions, 768t, 768
Photoluminescence, 504, 504f
Photons
  photoelectric effect and, 215f, 215–216
  quantitized energy and, 214f, 214–216, 215f
Photoreceptor cells, 363
Photosynthesis, 197, 799, 991, 991f
Photovoltaic solar cells, 378
Physical change, 10

Spin states, 236, 237
Spontaneous processes, 176, 176*f*, 800–801*f*, 800–804, 803*f*
  confusing spontaneity of a process with speed, 800
  criterion for, 802
  defined, 800
  determining spontaneity, 858
  electrical work, 861
  how signs of ΔH and ΔS affect reaction spontaneity, 822*t*, 822–823
  identifying, 801
  irreversible processes, 802–804, 803*f*
  isothermal process, 803, 803*f*
  oxidation-reduction reaction involving zinc and copper, 847, 847*f*
  reversible processes, 800, 801*f*, 802–804, 803*f*
  temperature and, 800, 801*f*
Sp orbitals hybrid orbitals, 352–354, 353*f*, 354*f*
Square lattice, 471, 472*f*
Square-planar complexes, 1007*f*, 1007–1008
Square-planar molecular geometry, 344*t*, 345, 349*t*
Square-pyramidal molecular geometry, 344*t*, 345, 346, 349*t*
Stability, of organic molecules, 1022–1023
Stabilization, colloid, 551, 552*f*
Stable isotopes for elements, 898, 899*f*
Stainless steel, 480*t*
Standard atmospheric pressure, 394
Standard cell potential, 850*f*, 850–857, 851–852*f*, 853*t*, 856*f*
  standard reduction potentials, 851–852*f*, 851–855, 853*t*, 855*f*
  strengths of oxidizing and reducing agents, 855–857, 856*f*
Standard deviation, 23
Standard enthalpy change, 184, 186, 187–188
Standard enthalpy of formation, 184–185, 185*t*, 198
Standard molar entropy, 815*ft*, 815–816
Standard reduction potentials, 851–852*f*, 851–855, 853*t*, 855*f*, 860–861
Standard solution, 148
Standard states, 184–188, 185*t*, 187*f*
Standard temperature and pressure (STP), 399–400, 400*f*
Standing waves, 225, 225*f*, 230
Starches, 192–193, 193*ft*, 1050, 1050*f*
State, changes of, 10, 10*f*
State functions, 168–170, 169*f*, 170*f*
States of matter, 4–5, 5*f*
Statistical thermodynamics, 809
Steam reforming, 938
Stereoisomerism, 996–997, 996–997*f*
Stereoisomers, defined, 994, 995*f*
Sterling silver, 480*t*
Stock solutions, 145
Stoichiometry
  aqueous solutions, 147*f*, 147–151, 149*f*
  Avogadro's number and the mole, 95–98, 97*ft*, 98*f*
  chemical equations, 86*f*, 86–89, 87–88*f*
  chemical reactivity, 90*ft*, 90–93, 91*f*, 92*f*
  coordination numbers, 487, 489*f*
  defined, 86
  empirical formulas, 99*f*, 99–102, 101*f*
  equilibrium constant and, 630–631
  equivalent quantities in, 103–104
  formula weights, 93*f*, 93–95
  gas variables and, relating, 404–405
  limiting reactants, 106–108, 107*f*
  molecular weights, 93*f*, 93–95
  procedure for solving problems, 147, 147*f*
  quantitative information from balanced equations, 103*f*, 103–105, 104*f*
  reaction rates and, 569–570
  stoichiometrically equivalent symbol (≏), 103–104
  titrations, 148–150, 149*f*
Stomach acids and antacids, 134, 134*ft*
Straight-chain alkanes, 70, 70*t*
Straight-chain analog, 1026
Straight-chain hydrocarbons, 1025
Strategies for Success
  analyzing chemical reactions, 142
  book features, 32
  calculations involving many variables, 400–401

Zeolites, 505, 505*f*
Zero
  absolute, 18
  as significant figure, 24
  on temperature scales, 18
Zero-order reactions, 580–581, 581*f*
Zinc (Zn), 140*t*, 840*f*, 840–841, 847, 847*f*
Zinc blende (ZnS), 487, 488*f*
Zinc ion (Zn^{2+}), 64*t*
Zinn, Walter, 915
Zone-refining, 964–965
Zone-refining apparatus, 964*f*, 964–965
Zooxanthellae, 786
Zwitterion, 1043
Zwitterion molecule, 701

Common Ions

Positive Ions (Cations)

1 +

ammonium (NH_4^+)
cesium (Cs^+)
copper(I) or cuprous (Cu^+)
hydrogen (H^+)
lithium (Li^+)
potassium (K^+)
silver (Ag^+)
sodium (Na^+)

2 +

barium (Ba^{2+})
cadmium (Cd^{2+})
calcium (Ca^{2+})
chromium(II) or chromous (Cr^{2+})
cobalt(II) or cobaltous (Co^{2+})
copper(II) or cupric (Cu^{2+})
iron(II) or ferrous (Fe^{2+})
lead(II) or plumbous (Pb^{2+})
magnesium (Mg^{2+})
manganese(II) or manganous (Mn^{2+})
mercury(I) or mercurous (Hg_2^{2+})
mercury(II) or mercuric (Hg^{2+})
strontium (Sr^{2+})
nickel(II) (Ni^{2+})
tin(II) or stannous (Sn^{2+})
zinc (Zn^{2+})

3 +

aluminum (Al^{3+})
chromium(III) or chromic (Cr^{3+})
iron(III) or ferric (Fe^{3+})

Negative Ions (Anions)

1 –

acetate (CH_3COO^- or $C_2H_3O_2^-$)
bromide (Br^-)
chlorate (ClO_3^-)
chloride (Cl^-)
cyanide (CN^-)
dihydrogen phosphate ($H_2PO_4^-$)
fluoride (F^-)
hydride (H^-)
hydrogen carbonate or bicarbonate (HCO_3^-)
hydrogen sulfite or bisulfite (HCO_3^-)
hydroxide (OH^-)
iodide (I^-)
nitrate (NO_3^-)
nitrite (NO_2^-)
perchlorate (ClO_4^-)
permanganate (MnO_4^-)
thiocyanate (SCN^-)

2 –

carbonate (CO_3^{2-})
chromate (CrO_4^{2-})
dichromate ($Cr_2O_7^{2-}$)
hydrogen phosphate (HPO_4^{2-})
oxide (O^{2-})
peroxide (O_2^{2-})
sulfate (SO_4^{2-})
sulfide (S^{2-})
sulfite (SO_3^{2-})

3 –

arsenate (AsO_4^{3-})
phosphate (PO_4^{3-})

Fundamental Constants*

Atomic mass constant	1 amu	$= 1.660539067 \times 10^{-27}$ kg
	1 g	$= 6.02214076 \times 10^{23}$ amu (exact)
Avogadro's number†	N_A	$= 6.02214076 \times 10^{23}$/mol (exact)
Boltzmann constant	k	$= 1.380649 \times 10^{-23}$ J/K (exact)
Electron charge	e	$= 1.602176634 \times 10^{-19}$ C (exact)
Faraday constant	F	$= 9.648533212 \times 10^{4}$ C/mol
Gas constant	R	$= 0.082057366$ L-atm/mol-K
		$= 8.3144626$ J/mol-K
Mass of electron	m_e	$= 5.485799091 \times 10^{-4}$ amu
		$= 9.109383702 \times 10^{-31}$ kg
Mass of neutron	m_n	$= 1.008664916$ amu
		$= 1.674927498 \times 10^{-27}$ kg
Mass of proton	m_p	$= 1.007276467$ amu
		$= 1.672621923 \times 10^{-27}$ kg
Pi	π	$= 3.1415926536$
Planck constant	h	$= 6.62607015 \times 10^{-34}$ J-s (exact)
Speed of light in vacuum	c	$= 2.99792458 \times 10^{8}$ m/s (exact)

---

*Many of the fundamental constants were redefined as exact quantities in 2019 by the International Bureau of Weights and Measures (BIPM). These and other fundamental constants are listed at the National Institute of Standards and Technology (NIST) website: http://physics.nist.gov/cuu/Constants/index.html

†Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the International Union of Pure and Applied Chemistry (IUPAC) and the National Institute of Standards and Technology (NIST), but "Avogadro's number" remains in widespread usage and is used in most places in this book.

Useful Conversion Factors and Relationships

Length

SI unit: meter (m)

1 km = 0.62137 mi
1 mi = 5280 ft
= 1.6093 km
1 m = 1.0936 yd
1 in. = 2.54 cm (exactly)
1 cm = 0.39370 in.
1 Å = 10^{-10} m

Mass

SI unit: kilogram (kg)

1 kg = 2.2046 lb
1 lb = 453.59 g
= 16 oz
1 amu = $1.660539067 \times 10^{-27}$ kg

Temperature

SI unit: Kelvin (K)

0 K = −273.15 °C
= −459.67 °F
K = °C + 273.15
$°\text{C} = \frac{5}{9}(°\text{F} - 32°)$
$°\text{F} = \frac{9}{5}°\text{C} + 32°$

Energy (derived)

SI unit: Joule (J)

1 J = 1 kg-m^2/s^2
= 0.2390 cal
= 1 C-V
1 cal = 4.184 J
1 eV = 1.602×10^{-19} J

Pressure (derived)

SI unit: Pascal (Pa)

1 Pa = 1 N/m^2
= 1 kg/m-s^2
1 atm = 1.01325×10^5 Pa
= 760 torr
= 14.70 lb/in^2
1 bar = 10^5 Pa
1 torr = 1 mm Hg

Volume (derived)

SI unit: cubic meter (m^3)

1 L = $10^{-3}\ \text{m}^3$
= 1 dm^3
= $10^3\ \text{cm}^3$
= 1.0567 qt
1 gal = 4 qt
= 3.7854 L
1 cm^3 = 1 mL
1 in^3 = 16.4 cm^3
